The questions which come to mind in studying this material do not relate to the production of the books, which can only be characterized as quite excellent, nor are they of an entirely critical character. Beyond question, the Nuffield venture has already done good far beyond the strict boundaries of the experiment, and it seems certain to do a great deal more. But the scheme as set out here does bring a quite novel situation into teaching at the levels linked with major public examinations. Until now the examining boards have been scrupulous to describe their syllabuses as examining syllabuses, and to insist that these need only have minimal effect on the teaching syllabus, which should reflect the particular requirements of groups of children and the aptitudes and enthusiasms of those who teach them. This view has not commanded the assent of all teachers, for a large proportion submit that these syllabuses are so wide and so detailed as to determine teaching syllabuses as well (and there is a not negligible group who positively welcome this situation). Criticism is sometimes linked with the mistaken view that these syllabuses represent the productions of people not actively concerned with teaching at the relevant level.

and this view has persisted in spite of the clearest demonstrations, in reports of the examining bodies, of the undoubted dominance of teacher representation at all relevant stages of syllabus development. If nobody else can be stigmatized as "them", then it is those teachers who take a leading part in the formulation of examining syllabuses who, by this very act, have cut themselves off from many of their colleagues! One is bound to ask whether this separation of "us" from "them" can be avoided in Nuffield Physics.

The programme set out in the Nuffield Physics books is in fact a most detailed physics scheme, and it has been possible to contemplate so detailed a formulation mainly because the examining boards have been prepared to examine for the time being on the detailed scheme as it has been set out and as it has been required of those taking part. There is thus the danger that this precisely laid out scheme of teaching could become an orthodoxy far more rigid than anything we have yet known. Those who have worked on the Nuffield Projects are well aware of this danger and are determined, as far as they are able, to prevent it developing. They would claim that so great are the changes which they have envisaged and which are incorporated in this detailed programme that it is necessary to bring everybody to a common starting point in the scheme. As time goes on they would hope to see changes within the whole operation of teaching derived from the project, exhibiting those features of difference which must develop if the scheme is to adapt to the needs of widely different groups of children and of teachers of a variety of outlook. It may well be that some of the most cherished sections of the small group who developed the programme will before long be removed completely

In the hands of the abler teachers the future of the project is most promising. Such teachers are not only those whose whole training has brought them to a position where their sympathy with the project is almost assured, but also a vast number, however trained, whose liveliness and sympathy of mind are drawn out by the stimulating discussion of the Nuffield books. It remains to ask what will be the effect on weak teachers. Here conclusions are bound to be speculative but it can well be argued that, as long as the effort is made, the teaching of a great many and probably of most of those not by nature gifted physics teachers ought to be much improved. For such people the books, and the teachers guides in particular, should be matters of deliberate and painstaking, but nonetheless illuminating, study.

One is bound to await the future development of the first generation of Nuffield pupils with interest. their experience have inclined them towards or against further studies in the physical sciences? generalize as easily as others, and when the time comes when substantial reliance on book learning becomes inevitable how will they react to it? These problems are pressing, for the extent to which the Nuffield methods supersede or become incorporated in general practice is a matter of urgency.

On the limited scale of the Nuffield experiment, schools undertaking the work have been equipped for particular subjects in a manner which no one could describe as lavish but which nonetheless has involved expenditures a good deal greater than those normal for groups at this level. If Nuffield procedures become the "norm" local authorities, however willing, may find it difficult to equip on this scale and it is to be hoped that those concerned with the finance of school equipment are already sharply aware of this It is unfortunate that it arises at a time of financial stringency, but, in a community where relatively complex pieces of apparatus of all sorts are becoming a commonplace of normal life, the material with which the average boy or girl has learned the systematics of the subject has not been expanded to anything like the same extent. At a time when the systematic study of science of any sort is falling short of the apparent needs of the country, if Nuffield were not the stimulus for re-equipping some other would no doubt have to be sought.

AN ILLUSTRIOUS NAME

The Electrical Researches of the Honourable Henry Cavendish

Edited by J. Clerk Maxwell. Pp. lxvi+454. (London: Frank Cass and Co., Ltd., 1967.) First published 1879. 1268.

"His name will be an object of more veneration in future ages than at the present moment. Though it was unknown in the busy scenes of life, or in the popular discussions of the day, it will remain illustrious in the annals of science. which are as imperishable as that nature to which they belong, and it will be an immortal honour to his house, to his age, and to his country." In this way, Humphry Davy spoke of the Hon. Henry Cavendish in 1810, the year of Cavendish's death. This is an ironical prediction, for it was all too literally true. What scientist does not know of the legendary Cavendish laboratory in Cambridge named after Henry Cavendish? Yet its prestige deservedly rests on the achievements and distinctions of such holders of the Cavendish chair as Maxwell, Rayleigh, J. J. Thomson, Rutherford and others. But Henry Cavendish himself is shamefully neglected.

Davy's prediction is, in fact, doubly ironical, for although Cavendish established for himself a considerable reputation on the strength of his published work, it was only well after Davy's lecture that his unpublished manuscripts came to light with startling record of independent discovery and anticipation of results which

appeared up to sixty years later.

Although Cavendish's researches covered a remarkable number of fields, for example, the chemistry of gases. heat and thermometry, meteorology, and gravity, his electrical studies most potently indicate his remarkable ability in quantitative experiment and his persistent conceptual insight. In his lifetime, Cavendish published only two of his papers on electricity. The first, "An Attempt to Explain Some of the Principal Phenomena of Electricity by Means of an Elastic Fluid', published in the *Philosophical Transactions* of 1771, supposed that electrification was the disequilibrium of the "electric fluid the particles of which repel each other and attract the particles of all other matter with a force inversely as some less power of the distance than the cube". This impressive paper, in which Cavendish established the consequences of that assumption, left the scientific community with the impression that this was as far as the already distinguished experimenter could get with the topic. Before two years were up, however, he had demonstrated the inverse power to be "between that of the 2+1/50 and that of the 2-1/50th". This conclusion and the experiments behind them he never published. The second published paper. "An Account of Some Attempts to Imitate the Effects of the Torpedo by Electricity, which appeared in the Philosophical Transactions of 1776, is deceptive in its title, for in the course of it he reveals a clear distinction between the "intensity of charge" and the "quantity of charge". "The idea" (of intensity as used by Cavendish). Maxwell tells us, "is precisely that of potential". Further. he argues for the law of divided current, and in support of this brings quantitative results of experiments on the resistances of sea water, iron and so on. These understated comments appear now, of course, rather like the tops of icebergs. For behind them lay a wealth of experimentation. He studied the distribution of electricity on conductors and was led to a clear conception of electrostatic capacity. He compared the charges in "electric substances coated in the manner of Leyden phials", which work led him to recognize specific inductive capacity more than sixty years before Faraday's independent discovery in 1837. His experiments on the resistances of solutions enabled him to deliver an anticipation of Ohm's law for currents.

Cavendish's researches provide brilliant examples of the way in which theory and experiment progress hand in hand. For Cavendish did not owe discoveries to the development of new electrometers or other technical devices. His advances were based on the application of a brilliant theoretical mind to the devising of simple but subtle experiments. His distinction of "intensity" from "quantity" of electricity enabled him to derive exact quantitative results with apparatus no more sophisticated materially than that used by earlier qualitative researchers such as Franklin. The most striking example of this is in his use of his own body as a "galvanometer". In comparing the resistances of solutions he discharged a Leyden jar through his body through a length of solution in a tube, which he varied by altering the separation of the electrodes inserted at each end. When he felt that the shock was indistinguishable from that from the same Leyden jar through an invariant "control" solution, he varied the length of the test solution until the shock was just noticeably greater than that through the control. He repeated this variation until the shock was just less and took the mean of the two readings as the length of test solution which had the same resistance as the control. Maxwell pointed out that these results were obtained "more than forty years before the invention of the galvanometer, the only instrument by which anyone else has ever been able to compare electric resistances". Indeed, "Cavendish was his own galvanometer".

Cavendish's electrical researches have previously had two editions. This third impression is extremely valuable, as the older volumes are not easily obtained. Clerk Maxwell provided an extensive introduction and account of the researches, together with characteristically analytical notes. The index, part due to Cavendish himself and part to Maxwell, is highly detailed and a valuable guide. Almost a dozen facsimiles of Cavendish's hand-drawn figures are included. This new edition will, hopefully, inspire for Cavendish himself "more veneration in future ages than at the present moment".

J. M. NICHOLAS

BACKGROUND TO NEWTON

Theories of Light

From Descartes to Newton. By A. I. Sabra. (Oldbourne History of Science Library.) Pp. 363. (London: Oldbourne Book Co., Ltd., 1967.) 70s. net.

DURING the seventeenth century, a few crucial fields of scientific enquiry became fully matured; among these were mechanics, pneumatics and optics. In studying the work then done in those fields, the historian is not forced to apologize for the chances missed, and the apparent blunders committed, by the great men. He can scrutinize the work done, and judge it by the criteria of adequacy of modern physical science; and after making allowance for the state of knowledge and technique of the time, he can exhibit it as genuine science of a high order of excellence.

The perceptive historian will, however, observe that the style of that scientific work was not quite the same as our own; the greatest men were, in name and in commitment, "natural philosophers". And so their technical work was influenced by their deepest views on method and metaphysics. The influence was not a simple one; for no piece of concrete scientific research can be merely the application of the preassigned method, or the simple illustration of an ontological scheme. The inevitable tensions between principle and practice are further complicated by the social dimension of scientific work; what an author says to his audience will be strongly conditioned

by his assessment of the terms of the dialogue and the point he wishes to establish.

In this study of one line of development of optics, Dr Sabra has done this sort of history supremely well. With a thorough mastery of the historical sources, he has analysed the arguments of the protagonists of the great debates on the properties of reflected and refracted light, and the phenomena of colours. In reconstructing Descartes's theories, and exhibiting the ambiguity of the crucial term "determination", he is able to explain the controversy with Fermat, and also to settle the vexed question of Descartes's originality. His study of Newton's early work in optics appears after a spate of recent research by others, and does not bear the same excitement as the earlier sections. But here, too, he illuminates the history by a well documented demonstration of a thesis: that Newton's interpretation of his "crucial" experiments was governed by his prior commitment to the corpuscularity of light, and to the nature of colours as unchanging qualities of these corpuscles. The work of Fermat and Huyghens and Hooke is also studied closely, as befits their role in the development of optics between Descartes and Newton.

Throughout the narrative we have a cluster of empirical questions (on reflection, refraction and colour), each giving rise to mathematical formulations and physical interpretations, but these latter being conditioned by methodological and philosophical principles. The statements of methodology are exhibited at length, analysed and related to what was actually done. Also, the empirical questions move in a natural sequence, following the points of significant advance: reflection and refraction dominating the earlier part, and colours the later.

This choice of topics indicates the boundaries imposed by the author on his study. For we have, in effect, the history of those particular problems in the matured science of physical optics, the investigation of which culminated in the published researches of Newton. history is genuine, and will appear entirely natural to a modern scientifically trained reader. But this approach applies equally well to the nineteenth century, when the deepest advances in natural science were still conditioned by philosophical commitments. In the seventeenth century, when a field such as optics was just achieving full maturity, it was still in the process of identifying its soluble problems, and putting the others to one side. The concentration on "light" to the exclusion of "sight" was effected only after Kepler and Descartes; and the philosophical problem of the nature of colours had a far more complex and important history in the period before Newton than the author indicates. Moreover, the study of light as a physical agency, not merely causing but also organizing changes in matter, was of great importance in that century; and of this we hear nothing.

The lack of specification of topics such as these which have been excluded from this study may give the reader the impression that this work is "the" history of theories of light in the seventeenth century. The author explicitly disclaims any comprehensiveness for his study; but he is responsible for his judgments of historical significance. In his restriction to the successful, "real" scientific problems in optics, he has lost some of the special atmosphere of that heroic century of the creation of modern physical science.

J. R. RAVETZ

ONE MAN'S ETHNOGRAPHY

Kwakiutl Ethnography

By Franz Boas. Edited by Helen Codere. Pp. xxxvii + 439. (Chicago and London: University of Chicago Press, 1966.) \$12.50; 90s.

THERE are anthropologists who have a preference for armchair anthropology: "theory at all costs" is the motto

of the extremists in this category. In contrast are the ethnographers for whom facts inhibit general comparison and a wider understanding. The marrying of fact and theory, the utilization of one to investigate the other in experimental field research, has unfortunately been a rarer accomplishment. Franz Boas, one of the most famous of anthropologists and master of many brilliant scholars, must be included in the category of born ethnographers.

Boas began as a physicist-geographer whose first contact with primitive culture was in the Arctic, where he went in 1883 to make maps and observe the effects of climate upon the Eskimos of Baffinland. Fascinated by his experience, he decided to change to the study of human He emigrated from Germany to the United States, took up an academic career and made his second field of study the Indians of the Northwest Coast, notably the Kwakiutl of Vancouver Island and the adjacent

Altogether Boas spent two and a half years in this area, making thirteen field trips between 1886 and 1931. The total time spent in the field was not excessive by modern standards and his visits were more widely spaced than usual. In between he worked on the language and on texts, conducting a long correspondence with George Hunt, a Kwakiutl informant of outstanding talent. He also brought informants to his home. The result was an enormous output of articles. Codere in a useful bibliography lists 174 items.

The nature of Boas's writings, of which his last work, Kwakiutl Ethnography, is typical, stems from his contention that: "It is our serious purpose to understand the thoughts of a people, the whole analysis of experience must be based on their concepts, not ours" (xviii, Introd.

Kwakiutl Ethnography).

Boas tried to achieve this aim partly through scrupulous field work and partly through the collection of texts. In field work he set stringent standards for himself at a time when anthropological field methods left much to be desired. He was in this respect a pioneer. He also originated the use of phonetically written texts for linguistic and ethnographic purposes. More than 3,000 pages of Kwakiutl texts have been published and he turned himself into a competent linguist in order to give a word for word translation. By the use of verbatim reports he sought to eliminate the distortion which he considered unavoidable in descriptions of culture by field workers of an alien culture. His aim was to get down to basics, for he considered that texts were never out of date although theories might be.

The aim of making the most massive collection of reliable data, the extreme concern to eliminate cultural bias and the sense of the overwhelming complexity of culture, all contributed to inhibit the development of a theoretical or comparative approach. Although theoretical formulations and a coherent description of Kwakiutl society and culture might have been his ultimate goal, Boas placed too many obstacles in the way of its achievement. Consequently, we are left with a body of verbatim reports and translations with a minimum of explanation, interpretation or analysis. Boas never reached the point at which he felt able to synthesize or interpret his rich

Kwakiutl Ethnography presents more unprocessed material, derived from informants' statements rather than from Boas's own observations. Although it amplifies our knowledge of Kwakiutl traditional culture it still does not enlighten us on important institutions such as the potlatch or the localized kin groups. Indeed, references to the latter are contradictory and show that Boas never understood them. To the end he remained the great ethnographer, never coming to terms with the theoretical possibilities which anthropology was offering, especially during the latter part of his career.

885

Boas was working on Kwakiutl Ethnography when he died in 1942. The incomplete manuscript was eventually passed to Helen Godere, herself a well known Northwest Coast scholar, for editing as a posthumous publication. Codere has written a useful introduction in which she discusses Boas's theory of ethnography and gives details of his field research. In addition, she has tried to make the manuscript more complete.

Chapters are prefaced by editorial notes referring to other Boas publications on the same subject- an invaluable device for those wishing quickly to consult everything of importance on that particular topic. In addition. she has included sections from various other works by Boas and combined them with the chapters of the manuscript in order to fill the gaps. She has clearly stated her editing methods and wisely confined her additions to selections from Boas's later publications which yield his most experienced and considered results. The eleven chapters relate to technology, social organization, the potlatch, war, religion, winter ceremonial, mythology, the arts and the life cycle. There are various appendices, a AUDREY BUTT bibliography and an index.

DEVELOPMENT IN THE PAST

Essays in the History of Embryology and Biology By Jane M. Oppenheimer. Pp. ix+374. (Cambridge. Mass., and London: The M.I.T. Press, 1967.) 100s.

This valuable book is a collection of essays dealing principally, and I wish it had been totally, with the history of embryology, a subject on which Professor Oppenheimer is admirably qualified to write. If she makes, as she certainly does, considerable lapses in dealing with the eighteenth and earlier centuries, this can be excused by the extreme unreliability of most of the extant secondary sources.

She can scarcely be expected to know how fanciful is the notion that St Augustine's theories of simultaneous creation and of rationes seminales constitute "a theory of emboîtement"; nor can she be severely consured for failing to discover that Aromatari's preformationism has been read into a text which gives it no serious support. Fortunately, the scholarly work of Adelmann has made it possible for her to condemn the absurd accusation against Malpighi that he was able "to see one thing and believe another" (Cole, F. J., Early Theories of Sexual Generation, 48; Oxford, 1930).

I could wish that she had given some attention to Swammerdam's excellent Historia insectorum generalis; though I hesitate to say that so knowledgeable a person does not know the work, it seems to me probable that she was misled by the title, which gives no indication that the book is entirely devoted to observations on the development of insects.

Even when studying the biology of the nineteenth century, the temptation to rely to some extent on secondary sources is difficult to resist, the field being so large: but it is unfortunate that Professor Oppenheimer has been led to rely on Rádl's Geschichte der biologischen Theorien, of which the two volumes appeared respectively in 1905 and 1909.

Rádl's treatment of Nägeli, Weismann, Roux and Mendel now seems both inadequate in length and totally mistaken in emphasis. What he says about Weismann, indeed, seems explicable only on the assumption of some personal animosity.

It is much to be regretted that Professor Oppenheimer appears to have been persuaded, whether by Rádl or otherwise, that it was not worth while to devote attentive study to Weismann's work. It may be a consequence of this neglect that she has been led to attribute to Roux

an adhesion to the Roux-Weismann hypothesis, which Roux himself strenuously repudiated. Unless I am grossly mistaken, his contribution to this hypothesis was limited to the idea expressed in his brochure *Ueber die Bedeutung der Kerntheilungsfiguren*, of 1883; an idea which, it is true, when rigidly developed led to the hypothesis, but which was so developed only by Weismann.

In reading Roux's embryological work it has seemed to me particularly striking that from first to last there is no evidence that he ever believed that development must necessarily follow the rigid mosaic form entailed by the Roux-Weismann hypothesis. If I have dwelt on this matter, it is because Professor Oppenheimer has a great admiration for Roux, who well deserves it; and I should like to convince her that she needs not to attribute to him this particular foible.

A short review must necessarily appear over-critical, for it is impossible to characterize in a few words the general merit of a book. I can only say that this book should be read by anyone engaged in the study of the history of embryology. Among many other advantages, it possesses that of calling attention to the admirable work of Boveri, and to the great merits of Driesch's Analytische Theorie der organischen Entwicklung, of 1894. Among the persons who failed to appreciate this work, the one who might most greatly have profited by it was Driesch himself.

Professor Oppenheimer's book implicitly calls attention to the impossibility of dealing with the more recent history of biology without an extensive knowledge of the German language. This, it is abundantly clear, Professor Oppenheimer possesses, though there are a few oddities in her translations.

J. S. WILKIE

PLAINS INDIAN RELIGION

O-kee-pa: a Religious Ceremony and Other Customs of the Mandans

By George Catlin. Edited with an introduction by John C. Ewers. Centennial edition. Pp. vi+106+13 plates. (New Haven, Conn., and London: Yale University Press, 1967.) 90s.

In 1832, George Catlin spent about three weeks among the Mandan Indians on the upper Missouri River, during one of his trips to record in paint the rapidly changing life of Indians on the American frontier. Despite the brevity of his visit, he had the good fortune to attend the major Mandan religious ceremony in the company of capable interpreters. This volume reprints his fourth published description of what he saw, written many years later. The credibility of Catlin's earlier accounts had been attacked, because of his frank descriptions of ceremonial selftorture and ritual sexual intercourse; because he had blamed the fur traders for the introduction of smallpox among the Mandan in 1837 and exaggerated (although only slightly) its devastating effects; and because he related his ethnographic materials to a bizarre theory of early Welsh influence on Mandan customs, language and physical type. In 1867, Catlin answered his critics by presenting a more complete description and by printing testimonials to his accuracy. As Ewers makes clear, Catlin's general reliability is confirmed by the briefer accounts of earlier and later eyewitnesses, and also by the much more complete and comprehensible material provided by A. W. Bowers, an anthropologist who interviewed aged Mandan in 1930-31, forty years after the last performance of the Okeepa.

Comparison of the coloured plates in this edition with the original photolithographs shows some loss in sharpness of definition and in colour tones, but in only one case (plate 12) is any significant ethnographic detail obscured in the reproduction. But Catlin's paintings and engravings are notoriously variable in reliability, partly because of his practice of reworking the same material for many years after his original field work. Thus the thirteen lithographs in this work should be compared critically with the four paintings of the Okeepa which Catlin made while he was still in the Mandan village, and with his other surviving Mandan paintings. It is unfortunate that Ewers has not attempted this here, for his own previous studies of other paintings of Plains Indian subjects provide the best demonstration of the methods which must be applied in evaluating illustrations as historical ethnographic documents. The text, also, must eventually be compared in detail with Catlin's three earlier accounts of the ceremony.

Catlin in 1867 held back some of his descriptions for a "folium reservatum" printed on tinted paper for the use of "scientific men". By 1950, when Bowers published in the University of Chicago's Social Anthropological Series, scientific women were also interested, so he turned to his wife for help in "toning down the accounts of the buffalo-calling rites with their sex licenses to make them readable without embarrassment to mixed audiences". In 1967, Ewers removes some of the sensationalism from this striking feature of Mandan ceremonialism (and indeed of Mandan trading behaviour) by explaining it in terms of general Plains Indian concepts of supernatural "power" and its transmission. The self-torture so vividly described and illustrated by Catlin was shared by other Plains tribes, among whom it was a central element of the widespread Sun dance. Other features which Bowers adds to the Okeepa as described by Catlin also fit it into a Plains context and make it appear to be a deviant form of the Sun dance: the prominence of sacred bundles, the quest for visions, ceremonial distribution of property, sponsoring of the ceremony by a single individual, the importance of clans, and other characteristics. Seen thus, the Okeepa may be remarkable in its complexity and the explicitness of its symbolism, but it is by no means exotic among Plains Indian rituals. Even Bowers's minimally theoretical ethnography maintained that Mandan "ceremonies were native dramatizations of the sacred myths", of which he collected several examples relating to the Okeepa, and so this would be an excellent place to test the utility of modern structural analysis of myths, ritual and symbolism as a tool for evaluating fragmentary and partly contradictory historical evidence, while reconstructing a consistent patterned description of the ceremony. This new edition of the basic eyewitness account, with the editor's helpful introduction and annotation, should promote the attempt.

WILLIAM C. STURTEVANT

MORE ABOUT STONEHENGE

Stonehenge of the Kings

A People Appear. By Patrick Crampton. Pp. 171. (London: John Baker, 1967.) 45s. net.

The author of this book asks "Palace? Temple? Fort? Computer? Calendar? What is Stonehenge itself, the building?" He himself sees it as a place where inauguration feasts of local chieftains took place. "It is in this sort of ceremony and in the seasonal festivals presided over by the king that I see the function of Stonehenge... nothing so far points to Stonehenge itself being a utilitarian building, and I think that in its heyday it was the focus in the Stonehenge capital at which the people of southern Britain convened and through a seasonal peaceful assembly expressed overlordship and power... I see it as the fit setting for a king to perform his practical and magical ceremonial functions."

All this is possible; no one in his archaeological senses has ever denied that Stonehenge was a place of assembly, and to guess whether that assembly was religious, magical, or secular is to waste time. We do not know, and in the present state of our knowledge of prehistory we cannot

know. That it was a computer or a calendar has not been proved by Gerald Hawkins or any others to the satisfaction of prehistorians. It is clearly not a house or a tomb. Stonehenge is very probably a ritual assembly place as has been said since John Aubrey in the seventeenth century thought that the people who ritually assembled there were the Druids. I certainly do not find it, as Crampton says, "the most enigmatic building in the world". It is a tour de force in the tradition of the stone and wood henge monuments which were a part of the life of the society of third millennium B.C. England.

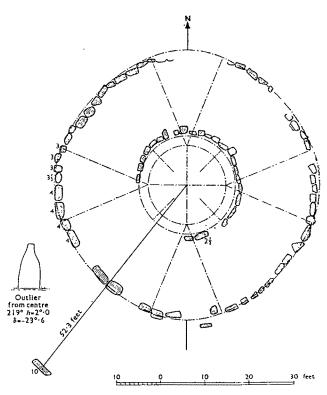

Mr Crampton is obsessed by the excavation of Clickhimin and the excavator, John Hamilton, will blush when he reads that his dig was "probably the most illuminating excavation ever carried out on a structure of barbarian northern Europe". The broch of Clickhimin in the Shetlands is now claimed by Crampton as something which "may prove to be the 'Mycenae' of northern. barbarian Europe". The excavator uncovered the internal structure of an earlier stone-built fort dating from the fourth to the second centuries B.C., and Mr Hamilton wrote of it, "For the first time, the domestic arrangements inside such an early Celtic fortress were completely revealed". Of this modest and correct statement, Mr Crampton writes: "His expansion of this humdrum statement is perhaps one of the most important advances in British archaeology—I am inclined to think the most This Clickhiminomania dominates the argument of this book. What was proved to exist in the immediately pre-Roman centuries in the north of Scotland was, we are told, the rule for all prehistoric Britain: "the illumination shed by Hamilton's excavation on barbarian Europe will be no less than that Schliemann shed on early Greece . . . a historical discovery difficult to over-assess in its importance will have been made at the prehistoric fort at Clickhimin".

Seeing the prehistoric world of Britain with Clickhiminstained spectacles, Crampton assumes that Woodhenge and our other henge monuments were two-storeyed dwellings inhabited by a royal, tribal household similar to that of Tara, but adds that this pretence may seem "wild". Admittedly, he was writing before Dr Wainwright's 1967 excavations at Durrington Walls-but then he might have turned those temples into two-storey dwellings and Durrington into a prehistoric city. He has a vision of second millennium Britain. "I see Wessex as an area of wealth and power dominated by five heroic communities. I see five kingdoms ruled from nucleated capitals at Lambourn, Avebury, Stonehenge, Oakley-Knowlton, and Dorchester . . . I see the populations of the tribal capitals living in drum-tower, timber forts, two or more storeys high, some of the henges and barrows being the surviving remains of these. I see these structures housing a hundred up to considerably greater numbers in each."

The author is entitled to his private visions, but he must not expect those of us who spend our lives studying the third and second millennia B.C. in Britain to substitute his personal view for the archaeological facts. This is a very unfortunate and unworthy addition to the long list of books written about Stonehenge. The general reader should not be taken in by its good production and many well-done plates and figures. It is full of errors: plate V, for example, is one of the well-known kerb-stones at Newgrange with interlocking spirals and lozenges and chevrons. We are told that similar motifs occur "in large numbers" in the tombs of Ireland, Brittany and Spain. I, who spend a large part of my life constantly studying mural megalithic art, would be glad to know of one example—apart from Gavrinnis—in Brittany or Spain. The "large numbers" are fictitious, and so, alas, is much of the book. Surely we are, in prehistoric archaeology, past the stage when personal guesses can be elegantly dolled up in books costing more than two pounds. We can all guess at the past, but we should present our guesses—however wild and at first sight improbable—with moderation, scholarship, and an understanding of what is at present known about prehistory. This Mr Crampton does not do.

GLYN DANIEL

MEGALITHIC SITES

Stone rings at Easter Delfour, from Megalithic Sites in Britain, by A. Thom (Oxford University Press; 63s.). The maximum outer diameter of the rings is 22 megalithic yards. In the book the megalithic yard, which measures 2.72 ft., is established as the basic unit of measurement in megalithic Britain, and is used in an astronomical interpretation of the function of these sites.

ENGLISH MEDIEVAL MEDICINE

Medicine in Medieval England

By C. H. Talbot. (Oldbourne History of Science Library.) Pp. 222+8 plates. (London: Oldbourne Book Co., Ltd., 1967.) 35s. net.

DR C. H. TALBOT, Research Fellow at the Wellcome Historical Medical Museum and Library, is well known for his studies of Anglo-Saxon and medieval medicine in England. In this book he writes on these subjects.

In the first chapter on Anglo-Saxon medicine he notes that after the conversion of the Anglo-Saxons to Christianity (A.D. 597-670) important intellectual links were forged with Ireland and Gaul. Teachers and books were imported; schools, including those in which medicine was taught, were established, and the cultural level of the Continental seats of learning served as a standard for the English people. An expert bibliophile, he describes the books and writings on medicine from Greek, Latin and Arabic sources which, probably, were studied by Anglo-Saxon leeches and their students. Some of these were translated into Anglo-Saxon, and then the Anglo-Saxons wrote treatises of their own, like the papers collected in the Leech Book of Bald which has survived. The Anglo-Saxon libraries, especially that of York, were consulted and extolled by continental scholars; but they were pillaged

and burnt by the Scandinavian invaders, or much more would be known about Anglo-Saxon medicine. There was a partial revival of medical manuscripts under King Alfred. They are not numerous and are in the British Museum and at Oxford and Cambridge. "Touching for the King's Evil" and the use of magic, amulets and charms in Anglo-Saxon medicine are discussed.

A chapter on Arab medicine, which was based on Galen's works, and reference to the writings of Rhazes, Averroes and other Arabians follow. The third and fourth chapters describe the Universities of Salerno and Montpellier. Talbot shows that generalizations about the influence of Salerno on English medicine are not valid, for they do not take into account considerable differences which separate the earlier from the later productions of this school. In fact, the earliest use of a Salernitan text in England seems to have been in the twelfth century. He also finds no evidence for the phrase, adopted by many modern writers on historic medicine, Ecclesia abhorret a sanguine, as a reason for the separation of surgery from medicine. It does not appear in the Council of Tours, A.D. 1163, or any Decretal of the Popes. It dates from Quesnay of Paris in 1774. Montpellier, it may be noted, had a fully developed medical faculty by A.D. 1137.

The chief features of medieval medicine occupy the rest of the book. Medical education, preceded by the acquirement of a degree in arts, is the subject of the fifth chapter with special reference to the lengthy course at Oxford. In the next chapter an account is given of the work of Gilbertus Anglicus, one of the first English writers on medicine, and others. Reference is made to Roger Bacon's attack on the physicians of his time. The seventh chapter gives much information on medieval surgery. The rest of the book is devoted to chapters on John Gaddesden, on anatomy and its exponents, the ordinary medieval practitioners, medical ethics and etiquette as then practised, hygiene, epidemics, hospitals, and vernacular texts; the book closes with a chapter entitled "The Final Phase".

This summarized account indicates the wide range and depth of the book and the important contributions which it makes to medical history of the Anglo-Saxon and medieval periods. In a brief preface Talbot states that his book is addressed to the general reader, not to specialists. This is, however, the work of a scholar embodying his researches, and will also appeal to general and medical historians. The bibliography is meagre, and references are omitted purposely, although their inclusion would have been welcome to students of the periods. But Talbot has given us so much that it is perhaps ungracious to ask for more.

ARTHUR MACNALTY

FUEL AND FOOD

The Limits of Man

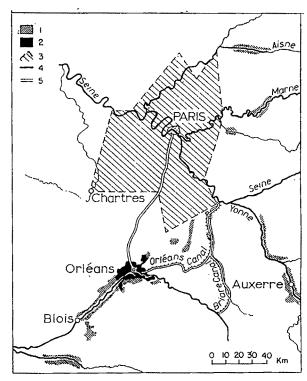

An Enquiry into the Scientific Bases of Human Population. By Hugh Nicol. Pp. 283. (London: Constable and Co., Ltd., 1967.) 35s. net.

Ir there are any people who believe that either in business or agriculture you can get something for nothing, they will probably be disillusioned by the time they have read Professor Nicol's repetitive refutation. Similarly, anyone who thinks that plants contain nothing but C, H and O will have the error thoroughly thumped out of him. These illusions may be widespread, but not, let us hope, in quarters where agricultural policy is established. Yet much of the book seems to be directed towards, or at, people in these places; it is a continuous editorial castigation of their misdirection of national and world agricultural policy with some bits of popular science and scientific history scattered through it.

The principal theme is that present agricultural policy relies too heavily on fossil fuels for the production of machinery and fertilizers, that ultimately these fuels will be exhausted, and that other methods of farming, for example, the use of clovers and other nitrogen-fixing legumes, deserve more attention. These are valid points, and it is good that people should comment on the way in which we are now squandering unrenewable resources, but agriculture is responsible for such a small part of the total waste that it seems hard that it should be singled out for special condemnation. No doubt, however, it is the duty of biologists to try to set engineers and physicists a good example.

The book is enlivened by many quotations—some pertinent and some comic. The most relevant is from R. G. Ingersoll: "In Nature there are neither rewards nor punishments—there are consequences". N. W. Pirie

WINE FOR PARIS

Provisioning of Paris with cheap wine in the seventeenth and eighteenth centuries (after Dion). I, Vineyards producing cheap wine. 2, Parishes in the Orléans district indicated in 1709 as being "all in vineyards". 3, Area around Paris in which wine production for sale to merchants and innkeepers had been prohibited in 1577. 4, Rivers used for navigation. 5, Paris-Orléans road. From An Historical Geography of Western Europe before 1800, by C. T. Smith. (Longmans, Green and Co., Ltd.; 65s.)

GREAT BIRD ARTIST

Thorburn's Birds

Edited with an introduction and new text by James Fisher. Pp. 184 (82 plates). (London: Ebury Press, and Michael Joseph, Ltd., 1967.) 50s.

ARCHIBALD THORBURN (1860–1935) is described in the introduction as having been "the first great bird artist of the twentieth century as well as the last of the nineteenth". In technical terms of book illustration, his work provides a bridge between the hand-coloured lithography of the earlier period and the methods of reproduction

used today. His work combined scientific accuracy with artistic merit, and he made his subjects look alive. With a few exceptions, he restricted himself to the birds (and sometimes mammals) of western Europe: he was in great demand as an illustrator both in Britain and on the continent. He also published four books of his own; and as an artist he was never better than in his British Birds, of which the four quarto volumes first appeared in 1915-16 (with a supplement in 1918). The pictures from that are here used again, and it is excellent that a new generation should have the opportunity of enjoying them.

The artist's original text was undistinguished and is now out of date. James Fisher has provided an entirely new one, in a novel and useful form. For descriptions he lets the plates speak for themselves, while he leaves habits to other works, and this allows him to concentrate on distribution. For each species there are, on the page facing the relevant plate, two paragraphs of compressed information. The first gives the world range, indicates the probable geographical origin, and mentions any seasonal movements. The second gives the status in Great Britain and Ireland—distribution within the area, size of population, changes that have taken place and current trends. The whole constitutes a valuable reference text both for ornithologists and for conservationists, the author's scholarship in these matters being of a high LANDSBOROUGH THOMSON

BRITISH LIBRARIANSHIP

Librarianship in Britain Today Edited by W. L. Saunders. Pp. xviii+173. (London: The Library Association, 1967.) 40s.

DURING the late summer of last year a three week course for librarians from overseas was held, at the invitation of the British Council, by the University of Sheffield Postgraduate School of Librarianship. The course included visits to selected libraries and lectures on topics of significance in the British library scene. The lectures presented during the course form this book.

The aim of the course was to provide a comprehensive

survey of present-day British librarianship: a formidable task even for a three week course. The fourteen lectures, given by leading figures in the profession, have met this requirement admirably. The editor of this book and director of studies for the course is to be congratulated on his selection of topics and the speed with which he has been able to publish. This up to date survey, even when the topicality of the papers has passed, will still have a value in presenting a picture of an exceedingly important stage in library development.

The scope of this book, however, is not as wide as its title implies. The content is governed by factors which determined the form of the course. First, the members of the course were expected to be from public and academic libraries, and second, the contribution made by the many visits cannot be included. The resulting exclusion of any detailed treatment of special librarianship is a deficiency which could have been remedied by the subsequent inclusion of additional papers in the book.

University librarianship receives detailed coverage with four excellent papers on the established and new universities, developments in the new technological universities and library buildings; together they succeed in partially filling an unfortunate gap in the literature.

The last two papers on "British Librarianship in the Next Decade", by civil servants in the Department of Education and Science, Mr P. H. Sewell, library adviser, and Mr B. J. Perry, senior scientific officer, OSTI, are of particular interest. In his contribution, Mr Sewell sees "the pattern of British library services as being more and more geared to identifiable community needs and departing in some respects from the institutional patterns with which we are familiar". Mr Perry also sees the development of "an increasing number of mechanized services ... [which] will be rigorously tested as to their suitability in meeting user needs . . .". Mr Sewell envisages the greater interdependence of libraries within specific areas with even in some cases integration of staffing between local libraries of different types. Mr Perry stresses the developments which should take place in the use and exploitation of mechanized bibliographical services and details the impressive work which OSTI is now undertaking in this field. Biological Science

BENEATH THE TUMOUR VIRUSES

Subviral Carcinogenesis

Edited by Yohei Ito. (First International Symposium on Tumor Viruses.) Pp. xvi+441. (Chikusa-ku, Nagoya: Aichi Cancer Center, Research Institute, 1966.) PRE- and post-congress meetings now surround a major international jamboree like satellites, and it must be admitted that they are often more rewarding to the specialists concerned than the main cong ess itself. The first international meeting of tumour virologists was organized at Negoya by Professor Ito and his colleagues after the Ninth International Cancer Congress in Tokyo, and the contributions have now been published under the title Subviral Carcinogenesis. The meaning of this title is a little obscure, but the volume contains a wide ranging series of papers extending from molecules to mice and occasionally to man.

Considerable progress has taken place in the characterization of tumour virus nucleic acids, as is clear from sections devoted to this subject. This particularly applies to the DNA-containing viruses, leading, for example, to the extensive homology studies with adenoviruses and to the detection of viral nucleic acid in "virus free" tumour cells. Even the RNA-containing tumour viruses which have been notoriously difficult to purify are now being characterized, and it is of interest that a variety which have been examined carry large and similar sized RNA molecules. There is a useful paper on the controversial problem of DNA participation in the biosynthesis of Rous sarcoma virus, an RNA virus.

The tumour cell antigens were also thoroughly covered. Some of the papers dealt primarily with the relevance to transformation mechanisms, including an authoritative contribution on the role of the papova virus T antigens. A particularly interesting Russian report concerns a newly discovered agent, whose sole manifestation appears to be the induction of a new skin transplantation antigen.

Several papers dealt with the important topic of defectiveness in tumour viruses and the dependence of one virus on another (in contrast to virus dependence on These concerned the classical Rous sarcoma virus and its helpers, complementation between DNA containing viruses, and the adenovirus SV40 hybrid virus.

In the case of the mouse leukaemia virus, progress has been rather limited, but recent developments, such as the spleen colony technique and the isolation of the associated mouse sarcoma virus, should lead to rapid progress in the coming years. The possible role of viruses in human cancer was only dealt with specifically in two papers, which stress the difficulty of interpreting the meagre findings. Progress obviously awaits a better understanding of the experimental systems. In addition to the papers directly concerned with tumour viruses, there was a scattering of other papers, some of which are particularly relevant to the tumour virus field, for example the account of bacterial conversion.

This book, which is a credit to Professor Ito and his Japanese colleagues, constitutes a useful and up to date collection of findings by leading virologists—or rather subviral oncologists.

MICHAEL STOKER

TUMOUR ANTIGENS

Specific Tumour Antigens

Edited by R. J. C. Harris. (A Symposium organized by the International Union Against Cancer and the USSR Academy of Medical Sciences.) (UICC Monograph Series, Vol. 2.) Pp. 366. (Copenhagen: Munksgaard, 1967.) 126 D. kr.

This report comprises thirty-four articles which in the main are summaries of groups of papers published in detail elsewhere and of which half emanated from laboratories in the United States or Soviet countries. The terminal discussions reflect the general doubt as to whether our available techniques are yet capable of defining completely the antigenic structure of normal tissue and therefore of differentiating tumour specific antigens. Thus Grabar appears convinced that azodye induced hepatomas in rodents are marked by specific antigens of which one component is an embryonal antigen (C.A.), but Deckers, working in the same field, notes the absence of embryonal antigens.

The significance of virus infections in experimental neoplasia and in the subsequent antigenic variation of the infected host cell is considered for a wide range of agents, including those associated with Rous sarcoma, Maloney lymphoma, Graffi and Gross virus-induced leukaemia, $S\bar{V}40$ and the adenoviruses. Melnick and Rapp analyse the complexity of virus transformation of cells by the use of metabolic inhibitors, such as cyclosine arabinoside which permits the synthesis of tumour antigen but arrests the production of SV40 viral antigen in monkey cell cultures. These authors and others report the formation, during cell transformation, of viral hybrids such as adeno-SV40 virus. The concept of immunity with regard to cancer is closely examined from the viewpoint of experimental pathology. Thus Harris, by the prior use of chicken tissue antigens for the induction of acquired immunological tolerance, reversed the normal rejection of Rous sarcoma virus-induced tumours in turkeys.

The sections of the report on human cancer studies include the immunological analysis by Korngold of serum gamma and macroglobulins. Sabin describes an unsuccessful search in the sera of children with early childhood tumours for complement fixing antibodies for antigens extracted from these tumours, but emphasizes the need for similar investigations using cytoplasm-modifying antibodies

Throughout the report doubts are expressed as to the validity of claims based on the use of immunologically heterogeneous systems for tumour specific antigens. Hence the interest which arises in the clinical report by Southam on the homotransplantation of human cell lines, including tumours, in healthy volunteers, the experimental production of hypersensitivity to autologous cell extracts in leukaemia patients and the effect of autologous fleucocytes or plasma on auto-transplants of cancer cells

in patients. Southam concludes that this approach has provided some support for the hypothesis that patients may develop an immunological defence mechanism. Surgeons have not infrequently come to a similar conclusion on clinical grounds, such as the occasional recovery to full health and survival for many years of patients with lesions so gross at operation that further surgical treatment other than a confirmatory biopsy was deemed unjustifiable.

The report conveys successfully the impact which cancer research has produced on the cross-linkage of experimental pathology, immunology, virology, biochemistry and genetics, and provides a valuable reference source. Perhaps of greater importance is the clear and refreshing demonstration that nations of different ideologies cooperate successfully in at least one area of human endeavour. Fitting tribute is paid in the foreword to the work of the Symposium organizer, Professor L. A. Zilber, who died in his laboratory in Moscow shortly after the meeting.

C. A. GREEN

HAEMS AT HOME

Hemes and Hemoproteins

Edited by Britton Chance, Ronald W. Estabrook and Takashi Yonetani. (Proceedings of the Third Colloquium of the Johnson Research Foundation of the University of Pennsylvania, Philadelphia, April 16 and 17, 1966.) Pp. xv+624. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1966.) \$13.75.

THE haemoproteins have been subjected within recent years to very intense study by physico-chemical techniques. They are peculiarly suited to the variety of approaches which are now available and progress in the field is rapid. It is important, therefore, that at suitable intervals the whole corpus of knowledge concerning them and their enzyme properties should be reviewed and related one to the other.

The first colloquium on haems and haemoproteins was convened by Professor M. R. Lemberg and held in Canberra in 1959. It was a great success and set the pattern for future conferences. The second colloquium took place in 1964 at Amherst and now the third has been held at the Johnson Research Foundation of the University of Philadelphia and is recorded in the volume being reviewed. In the words of the editors, "The colloquium was organized to honour M. R. Lemberg, H. Theorell, D. Drabkin and D. Goddard and especially to celebrate two landmarks in the study of haemoproteins—the late David Keilin's book on cell respiration and cytochrome and the fortieth anniversary of the studies by R. Hill and H. F. Holden on the resolution of haemoglobin". There were sixty-five participants, fifty-six presented papers and a number of specifically arranged discussions.

The range of subject matter covered may be gathered from the titles of the topics presided over by individual chairmen: "Structure and Reactions of Haem", "Reactions of Haem with Proteins", "Ligand Binding to Myoglobin and Haemoglobin", "Intermolecular Interactions of Crystalline and Soluble Myoglobin and Haemoglobin", "Structure and Reactivity of Hydroperoxidases", "Physical Properties of Cytochromes c and b_5 ", "Ligand Binding and Reaction Mechanisms of Oxidases", "Kinetics of Electron Transfer Reactions in Cytochrome c", and "Theoretical Interpretations".

Contributions and discussions are at a high specialist level. The emphasis throughout is upon the physicochemical approach except for the three papers and discussion debating the structure of haem a and cytochrome c oxidase. In a characteristically witty and penetrating postscript, entitled "The Forgotten Cell", D. L. Drabkin reminds us that biological systems have properties and present problems which are inherently important and he

warns against myopic preoccupation with purified artefacts!

Despite its price, this is a volume which no one working in the field can afford to be without and which to enzymologists should be of particular value. It is in the haemoproteins that the allosteric transformations of structure associated with enzyme activity can be most readily studied.

The volume is excellently produced, for which both editors and publishers should be congratulated.

C. RIMINGTON

FREEZE-ETCHED SPECIMENS

Freeze-etch view of the nucleus in an onion root tip. nucleus, showing the nuclear pores, is the darker region in the upper part of the picture. From Cell Ultrastructure, by William A. Jensen and Roderic B. Park (Prentice-Hall International; 16s.). The book contains a collection of electron micrographs of a wide variety of animals, plants and bacteria, and summarizes the knowledge of cell structure which the electron microscope has made available. The book is intended to supplement biology textbooks in elementary courses.

CHROMOSOMES FOR STUDENTS

Medical Cytogenetics

By Mihály Bartalos and Theodore A. Baramki. xxiii+419. (Baltimore, Md.: The Williams and Wilkins Company, 1967. Distributed in the U.K. by E. and S. Livingstone, Ltd., Edinburgh.) 100s.

THE advent of this expensive book was widely publicized. From the preface we gather that its authors regard it as a fitting climax to the developments in human cytogenetics since 1956. In the foreword, by a physician from the Johns Hopkins Hospital, the book is described as "a complete and authoritative overview". So the drums roll and the trumpets blare, but after reading the book I am tempted to make my exit at this stage, referring readers to the immortal last line of T. S. Eliot's The Waste Land.

This is not a book for scientists. It is addressed to the student (unspecified but presumably medical) and to the clinician, and also hopefully to the cytogeneticist. It is written by two clinicians, one a paediatrician and the other an obstetrician and gynaecologist, and it is in the classical genre of medical textbooks. The book consists of an uncritical assembly of a mass of statements which will only serve to confuse the medical student and the clinician. who are not in a position to distinguish the serious from the trivial or fact from fancy. Nor, unfortunately, do the authors provide much guidance.

There is little point in the inclusion in a book for nonspecialists of detailed minutiae, much irrelevant, relating to techniques. The authors, in fact, betray their unfamiliarity with techniques by advocating, for example, outmoded and clumsy photographic methods for counting and analysing chromosomes. They seem totally unaware that some who contribute much to human cytogenetics do not use them at all nor have ever used them. The statement in the chapter on the effect of radiations that "rings and dicentrics can be scored readily, even by those

with a minimum of training" speaks for itself.

Although there is a mass of detail there is much that is important which is barely mentioned. The classic work of Ford and Hamerton on human male meiotic chromosomes is dismissed in thirteen words, and there is no mention of Chu, Darlington, Makino and McIlree, who have made important contributions on this subject. There is a total failure to understand the significance of the work of Tjio and Whang on the direct bone marrow technique and why this method of preparing cells for analysis was such an important advance on the earlier short term culture technique for marrow. Autosomal structural heterozygosity, the commonest form of detectable aberration, is far from completely dealt with, and the authors betray their discomfort in their description of the possible products of the interaction at breaks produced in G_1 , S or G_2 . Chromosome mosaicism is a topic of considerable importance to the cytogeneticist and to the clinician who has the responsibility of dealing with chromosomally abnormal patients. Yet scant attention is given to chromosome count distributions and to the criteria for establishing the diagnosis of mosaicism, although these have been the subject of public debate since 1960.

This book cannot be commended save as a source book W. M. COURT BROWN of references prior to 1965.

SEX CHROMOSOMES

Sex Chromosomes and Sex-linked Genes

By Susumu Ohno. (Monographs on Endocrinology, Vol. 1.) Pp. 192. (Berlin, Heidelberg and New York: Springer-Verlag, 1967.) \$95.

Dr Ohno's book on sex chromosomes and their genes bears witness to the great deal of work on this topic, to which Dr Ohno himself has valuably contributed. The book is divided into three sections. In the first section it is shown how distinguishable sex chromosomes are thought to have arisen from morphologically identical chromo-This does not, however, necessarily imply a somes. strictly parallel evolution of sexual dimorphism from hermaphroditism. This evolutionary pattern is, of course, built up from comparison of chromosome morphology from present day animals. But the logical barrier in accepting the proposed sequence of past events inferred from present day appearances is swept aside by Olmo's persuasive enthusiasm in unfolding his thesis. Reference to Fig. 3, showing the evolution of snake Z and W chromosomes, will illustrate the type of argument used. Unfortunately, in this instance, no critical evidence is presented to show that the inversion, if it actually is one, is pericentric, even though this is crucial to Ohno's argument as to how chromosomal differentiation is initiated.

Admittedly the critical evidence may be unobtainable; even so Ohno's discussion of chromosomal evolution reveals the strength of this type of approach, yet he neglects its inherent weakness. Evolution of genomes is also dealt with; it would have been helpful if a diagram had been supplied to "fix" the mass of facts presented, relating taxonomic position with DNA value within this cytologically rooted evolutionary tree. The first section ends with a useful comparison of X and Z-linked genes between phylla. From the evidence presented it seems likely that both Adam and the Serpent carried similar genes on their sex chromosomes.

The second section deals with desage compensation and "lyonization" of X chromosomes. This is discussed from a biochemical, morphological and cytological point of view. No mention is made of scepticism of this phenomenon and newcomers to the field may perhaps like to read Grüneberg's views before completely digesting the interpretation.

How do the sex chromosomes determine sex? The last section attempts to answer this question and thereby to justify the book as a "Monograph on Endocrinology". But, as Ohno admits, no answers are forthcoming. This leads to an expectedly sketchy chapter on sex-determining factors. A second chapter on the development of gonads will, no doubt, resuscitate endocrinologists after the previous 160 pages of cytogenetics.

This is an attractively written and produced book and a veritable mine of information. Cytogeneticists will not be disappointed by Ohno's scholarship and authority. The many photographs and diagrams are of high quality although the photographs of Fig. 20 are unnumbered and should be viewed sideways on. There are a few typographical errors (for example, homozygous for homologous; page 102, end of first paragraph) and the potentially libellous phrase "mongolian idiocy" appears for Down's syndrome.

In all, this is a compulsively readable account of a subject hitherto badly in need of Ohno's capable treatment.

P. W. Barlow

NORMAL AND ABNORMAL CELLS

Practical Cytology

By R. G. W. Taylor. Pp. xi+148. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1967.) 39s. 6d.; \$7.

In clinical medicine the term cytology has come to have rather a special meaning, namely the examination of cells as an aid to diagnosis with some stress on the detection of malignant and benign growths of the female reproductive tract. It may also be added that the term has a euphemistic value when dealing with patients, and indeed even when giving extra-mural lectures to unsuspecting women's organizations. It is not surprising, therefore, that a book bearing the general title *Practical Cytology* should have a restricted content, being almost entirely concerned with smear techniques in medicine with a marked bias towards their application in gynaecological disorders.

The first chapter deals with the preparation of smears; the theory of fixation on which any rational approach depends is limited to a single sentence: "The principal requisite of a cytological fixative is that it shall precipitate the cell protein, and in particular the nuclear protein in a pattern characteristic of the form during life". The staining, mounting and examining of smears appear in the next chapter. Here the author seems unsure of the background of his readers; the opening page deals en passant with Papanicolaou's solutions, the Jenner-Giemsa method, Feulgen's stain and "it must be remembered that methanol fixation is a pre-requisite for all Romanowsky sequences". A few pages farther on, there are sections entitled "Cleaning Smears", "Loading the Slide Carrier", "Blueing Smears" and so on. There are numerous staining schedules,

with little explanation; but all rigidly and ponderously timed so that "most of the black magic associated with staining disappears".

A diagram of a general cell which marks the beginning of the third chapter is so abysmal as to defy further useful comment; it is also odd to see a detailed table designed so that the greater part of it actually appears upside down (the rest is printed sideways). This chapter, however, heralds the first of four others on normal and abnormal epithelial cells. The descriptions of the cells are clear and informative and there are some good, simple diagrams. The need for numerous photomicrographs has been recognized, but unfortunately these are generally of such mediocre quality that they do not help; none are in colour.

The last two chapters deal with documentation and ancillary techniques. There is a useful appendix and a brief bibliography.

The book really adds little to a subject which is itself fascinating and work which is rewarding.

D. LACY

MOLECULAR PHARMACOLOGY

Drugs Affecting the Peripheral Nervous System Vol. 1. Edited by Alfred Burger. (Medicinal Research: A Series of Monographs.) Pp. xxiii+620. (London: Edward Arnold (Publishers), Ltd.; New York: Marcel Dekker, Inc., 1967.) 220s. net.

IT is fashionable nowadays to add the adjective molecular to many of the normal subdivisions of biology, and it is a nice semantic exercise to consider what is meant. by this qualification in each of its various applications. Pharmacology is no exception and the expression "molecular pharmacology" is enjoying a current vogue although, rather more than in most cases, it is a tautology. Pharmacology has been faced with the problem, in its most acute form, of relating the biological and the molecular properties of drugs since its emergence as a separate scientific discipline in the middle of the nineteenth century. By using purely empirical procedures a great array of potent and useful drugs has been assembled, but our understanding of how these drugs act at the molecular level is still very slight, and has depended on collateral advances in other related subjects. This multi-author work collects together a great deal of experimental evidence and attempts a survey of the ideas and theories currently deployed. Attention is restricted to the peripheral nervous system—a further volume dealing with the central nervous system is promised—and consequently covers much the same ground as D. J. Triggle attempted single-handed in his Chemical Aspects of the Autonomic Nervous System. Although it appears more than a year later the literature survey is not much more up to date, but this is a much more substantial work and the overall coverage is more exhaustive.

The intention of the editor was to concentrate on the relationship between biological effect and chemical structure, but because of variations in the amount of material available and the personal preference of the various authors the balance of individual chapters varies within wide limits. The first chapter, by S. Ehrenpreis on cholinergic mechanisms, consists of a critical review of Nachmansohn's theory of the role of acetylcholine in nervous transmission followed by an interesting, if highly speculative, defence of the proposition that cholinesterase and the choline gic receptor are one and the same. At the other extreme is a very long chapter by L. Gyermek on ganglion stimulant and depressant drugs, which consists of an exhaustive review of the many structure—action studies carried out with ganglion preparations with virtually no theoretical discussion.

There are two rather cursory chapters on cholinesterase, but the remainir g articles on muscarinic and cholinolytic drugs, drugs acting on the skeletal neuromuscular junction, sympathomimetic and sympatholytic agents and drugs acting on sensory systems achieve a more even balance between the raw data of structure-action correlations and theoretical interpretation.

Most of the people working on these various areas of chemical pharmacology will be familiar with the general patterns of chemical structure variation that have been explored. What is most useful in this book is that the various theories which have been proposed are all collected together and extensively discussed. This survey shows that there is no shortage of ideas about the way in which chemical structure influences biological activity, but also clearly reveals the basic problem of chemical pharmacology—that it is extremely difficult to devise critical experiments to support or refute these ideas. Many intriguing problems are discussed and this collection of articles should prove very useful to anyone interested in this difficult problem of the relationship between chemical structure and physiological effect.

This volume is handsomely produced and printed; it is prefaced by an embarrassing piece of American mortuary prose that would have been better omitted; it is also very expensive.

E. W. Gill

ANTIBIOTICS GIVEN TREATMENT

Antibiotics

Origin, Nature and Properties. By Tadeusz Korzybski, Zuzanna Kowszyk-Gindıfor and Włodzimierz Kurylowicz. Translated by Edwin Paryski. Vol. 1: Pp. xix+1-1144. Vol. 2: Pp. xviii+1145-1651. (Oxford, London and New York: Pergamon Press, Ltd.; Warszawa: PWN-Polish Scientific Publishers, 1967.) 294s. net per set of two volumes.

WITH the explosive proliferation of published data in the field of antibiotics during the past decade, the need for an authoritative English language reference work, embracing combined knowledge of the many aspects of the biology and chemistry of those diverse compounds, has been keenly felt. These two volumes represent a most ambitious attempt to fill this gap, with the very large number of individual antibiotics listed providing its own tribute to the diligent application of the authors to such a herculean task.

The presentation, in view of the virtual impossibility of achieving an ideal classification of the antibiotics, is excellent, with the work being divided into seven main sections: antibiotics obtained from (a) the order Eubacteriales; (b) the order Actinomycetales, (c) Fungi imperfecti, (d) Basidiomycetes and Ascomycetes, (e) lichens and algae, (f) higher plants, (g) animal sources, of which the first two sections constitute the first volume and the others constitute the second volume. Further subdivisions are then made according to genus and on the basis of chemical structure, antimicrobial spectra and so on, as best suited. The presentation of many of the data in clear tabular form is a great advantage to the reader. While the inclusion of compounds derived from higher plants and animals as antibiotics is open to debate, it again underlines the wide coverage of the work.

The biological topics, which include accounts of the origin, culture conditions, isolation techniques, antimicrobial spectra, and clinical implications of the various antibiotics, are magnificently handled, as are considerations of stability, physical properties and so on. The copious cross-referencing within the various sub-sections, each of which has its own bibliography, is a most commendable feature. In view of this, it is all the more unfortunate that on the chemical side the work falls short of what might have been achieved.

The authors have largely ignored biogenetic aspects, as evidenced by the controversial statement in the introduction that the biogenesis of the antibiotics remains unclarified, and by the brief dismissal of the biogenesis of various specific compounds such as stipitatic acid and patulin in terms of statements to the effect that this has been studied. The failure to indicate the results of these biogenetic studies is most surprising, especially in view of the intense current interest in the topic as evidenced by the many published papers and by the appearance of several books devoted to this aspect alone.

An obvious attempt to update the original Polish version of the work has been made. This has led to some unfortunate situations, such as the clumsy insertion of the correct formulae for verrucarol and its close relatives with the retention of erroneous structures for the derived verrucarins and roridins, and the insertion of the correct formulae of the polymyxins with the retention of an erroneous table which complies neither with earlier spurious assignments of structure nor with the correct structural assignments of polymyxins B₁, B₂ and E₁. Even so, there are very few post-1964 references to original literature, amendments to the section on viomycin (where no evidence is presented in support of the revised structure) being a notable exception.

In some instances the chemical data are unreliable, indicating that, although the literature survey would appear to extend through 1964, its breadth in this area is suspect. Specific examples are the incomplete or incorrect structures given for iridomyrmecin (which incidentally, is misspelt), "polyporenic acid", geodin, ordin, solanocapsine, pleuromutilin, pristimerin and grifolin—to mention random examples—where the correct structures were all in the published literature by 1963, in some cases in the 1950s. The time interval occasioned by the translation and publication of the English version, of course, precludes the correct portrayal of the structures of important compounds such as fusidic acid, viridin, marasmic acid and hirsutic acid, and also precludes consideration of the stereochemistry and conformational aspects of the streptomycin molecule, as well as discussion of a number of more recently isolated antibiotics.

Portrayal of absolute stereochemistry by means of stereoformulae appears to have been done in a most arbitrary manner, and for important groups such as the penicillins, cephalosporins and tetracyclines there is no stereo portrayal at all.

Nevertheless, despite the shortcomings of these volumes on the chemical side, and in one or two other areas—as with the bacitracins, where more than the three bacitracins listed are known—workers in the many faceted area of antibiotic research will find it hard to resist their acquisition, for they provide a rapid and convenient source of comprehensive information and references to the original literature up to about three years ago. Purchase of both volumes is mandatory because the comprehensive authorand subject indices for the two are in the second volume.

M. MARTIN-SMITH

MURINE PATHOLOGY

Pathology of Laboratory Rats and Mice

Edited by Ernest Cotchin and Francis J. C. Roe. Pp. xxiii+848. (Oxford and Edinburgh: Blackwell Scientific Publications, 1967.) 155s.

THE Nuffield Foundation has recently become interested in the possible long term effects that food additives may have on human health. The screening of such substances to detect possible toxicity often involves tests on laboratory animals, and so the Foundation held a conference in 1966 devoted entirely to the pathology of laboratory rats and mice.

Two of the participants, E. Cotchin and F. J. C. Roe, have edited the twenty-four papers that were presented by recognized authorities and have produced a most comprehensive and welcome monograph.

Each paper is followed by an extensive bibliography, together with shortened versions of the discussions which succeed each paper. Although these bring the book up to date, they would have been easier to follow if they had been given under headings similar to those in the chapters.

It is appropriate that the first chapter should be devoted to the target organ of so many toxic substances, namely the liver, and it is encouraging to discover chapters covering hitherto neglected subjects such as the fungal infections, parasites and ophthalmic pathology of rats and mice, but it is disappointing to find that there are no chapters on bacterial diseases, cardiovascular diseases of mice and diseases of the lymphatic system. Although pneumonia and virus infections are adequately treated, salmonellosis, which is probably the commonest infection of these animals, is given barely one page, and even then only in passing.

The advantages of using specific pathogen free or disease free animals are amply demonstrated throughout and, in particular, the part that inapparent disease may

play in invalidating experimental results.

Several pleas are also made for the increased use of defined inbred strains or, as one author put it, "inbred mice are as indispensable to the biologist as pure chemicals are to the chemist". Yet, even today, people still ask for white mice!

There is little doubt that this book will be invaluable to both the animal pathologist and the producer of laboratory rats and mice; the former because it may enable him to decide whether any lesions that are found after death are due to the experimental procedures or naturally occurring disease, and the latter because the prompt recognition of disease and its diagnosis saves a great deal of time and money.

Although neither of the editors, both well known in their field, has contributed any of the papers, they feature prominently in the discussions, and must be congratulated for the excellent presentation, the many very good illustrations and the more than adequate index.

It is hoped that a companion volume will soon appear. covering the pathology of other species. JOHN BLEBY

RANGE OF MOLLUSCS

By J. E. Morton. (Biological Sciences.) Fourth, revised edition. Pp. 244. (London: Hutchinson and Co. (Publishers), Ltd., 1967.) 13s. 6d. net.

WHEN I was a student, work on molluses consisted of a largely anatomical survey related to hypothetical ancestral forms caught up in a variety of posturings from which some emerged with coiled shells, some with straight shells, some with none, some with torsion, some without. There was no hint, or hardly any hint, of the rich and exciting results of the work on functional anatomy which were to emerge later, although some of Orton's observations (which began it all) had already been long published and the first fruits of Yonge's magnificent extended study of these animals had been gathered.

Molluses are unusual animals, and, at least for some people, exciting ones. Their chief attraction is the quite extraordinary way in which they retain their characteristics of anatomy-and even of function-no matter how much their bodies become contorted in pursuit of some special adaptation, and it is the curious intimate mixture of anatomy and functioning in relation to adaptation for life in a particular niche that makes them such an absorbing study. It is a never ending study, too, for year after year something unusual is discovered even about the most ubiquitous type. Despite this, and despite the recent resurgence of interest in the phylum, there is at present only one book which has attempted a summary .of modern malacological work at undergraduate level: Morton's Molluscs, first published in 1958 and now appearing in a fourth, revised edition. The text has been extended to incorporate new material-most significantly, information about Neopilina, still not known when the first edition appeared, though Morton had bad luck here in being just too early to include it, and an expanded treatment of Wells' work on cephalopod behaviour. Perhaps the change for which most readers will be grateful is the increased number of illustrations, most in the Morton idiom, though still, I find, small considering the page size, and sometimes (as in Fig. 29, page 137) rather too complex.

There are some things I miss: I would like in particular to see an account of how the molluscan radula—a major feature of the group-works, not just of what it looks like; there is a lot of interesting work done on the behaviour of molluses other than cephalopods though not referred to here; and the account of boring by muricacean neogastropods oddly omits all reference to the most extensive and experimentally critical work on this topic-that of

Carriker.

These, however, are minor carpings aroused in my mind by not finding perfect a book which I should like to be perfect. Morton has made a bold and outstandingly successful attempt to get all the really important facts about the living molluse into very brief compass. My students tell me that they enjoy it and that he has succeeded in adding to his information some of the fascination which he, I know, and most malacologists have found in the study of molluses. But perhaps the credit for this should really go to the mollusc and not to the author. A. GRAHAM

LIFE IN WATER

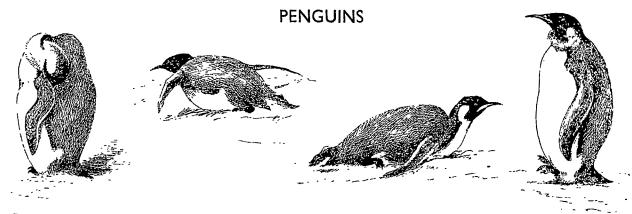

Oceanography and Marine Biology

An Annual Review. Vol. 4. Edited by Harold Barnes. Pp. 505. (London: George Allen and Unwin, Ltd., 1966.) 105s. net.

THE fourth edition of this annual review continues to navigate the hazardous waters surrounding a journal that attempts to serve a number of different disciplines, united by a common interest in the sea. Paradoxically, the biggest problem that it has to overcome is that which presumably it is intended to promote, namely, the exchange of ideas at the research level between the physical and biological sciences.

The first four reviews cover different aspects of physical oceanography. The article by W. Krauss on internal waves in the sea is a mathematical treatment of data collected at sea, and, apart from acknowledging the international reputation of the author in this field, comment is beyond my ability. In contrast, the paper by K. Wyrtki on the oceanography of the eastern Equatorial Pacific is a readable and informative discussion of the hydrography of this ocean, with particular attention paid to the problems raised by the recently This section is discovered Equatorial undercurrent. completed by an account of conditions governing the formation of ice in the Baltic by E. Paluso, and a record of some of the initial difficulties experienced in the organization of the international Indian Ocean expedition by R. Currie.

The origin, identification and distribution of gelbstoff in the sea are discussed by K. Kalle. This non-specific term is applied to a heterogeneous group of yellow compounds derived from the degradation of marine algae and also from humic compounds of terrestrial origin. is supplemented by a review of the extracellular products of algae by G. E. Fogg, dealing with compounds of smaller molecular weight which are more often studied in culture media. The important contribution of micro-organisms to the fertility of the sea is generally realized but little understood, and an interesting account of marine psychro-

Four views of the emperor penguin (Aptenodytes forsteri) from Birds of the Antarctic, by Edward Wilson and edited by Brian B. Roberts (Blandford Press; 105s.). Wilson took part in Scott's two Antarctic expeditions, and this book contains more than three hundred of the paintings and drawings which he made, together with notes about Wilson and his work and extracts from his journals.

philic bacteria by R. Morita describes metabolic studies that have been made on a group that thrive in conditions of temperature such as exist in the deeper parts of the oceans. The review by R. Scagel on the Phaeophyceae catalogues the extensive literature on this group but suffers from the lack of personal interpretation of the material presented.

Two articles have a palaeontological bias; that by R. H. Benson describing recent marine ostracods deals with living representatives of this order which is commonly preserved as fossils. The paper by H. B. Fell on ancient echinoderms in modern seas is a review of the author's own interpretation of echinoderm phylogeny, which, it should be pointed out, has not found universal acceptance among workers in this group.

Four papers dealing with aspects of animal behaviour are by J. A. Allen on rhythms and population dynamics of decapod crustacea; by E. W. Knight Jones and E. Morgan on responses to hydrostatic pressure; and by P. M. J. Woodhead, who examines the behaviour of fish in relation to light in the sea. He shows that in diurnal patterns of behaviour light has an important influence on feeding, sound production, spawning and schooling, and thus on the successful fishing of many commercial species. Lastly, J. Thompson discusses the biology of the grey mullets, and one is bound to comment on the poor quality of his Fig. 2 (page 306), which should not have escaped the vigilance of the editor.

The littoral ecology of tropical West Africa is reviewed by G. W. Lawson, who has wide experience in this field. Following Lewis's classification he has produced a guide to the flora and fauna of the principal ecosystems along the coast. Although his fauna list is by no means complete, it in no way detracts from this valuable synthesis which will stimulate further and more detailed studies.

The book is adequately provided with maps, figures and tables, but the references do not contain the titles of the publications, which are often required when requesting them on inter-library loan schemes.

Derek Dorsett

TEXT ON TAXONOMY

Taxonomy

A Text and Reference Book. By R. E. Blackwelder. Pp. xiv+698. (New York and London: John Wiley and Sons, 1967.) 150s.

NEARLY seven hundred pages about taxonomy cannot be expected to be easy reading, either for the specialist

or for the undergraduate. But Dr R. E. Blackwelder states in the preface to his new book, *Taxonomy*, that "It is specifically planned to be used as a textbook in two courses: a beginning course on the nature and practice of taxonomy and an advanced one, on the theory and technicalities . . ." Then again, also in the preface, he says, "It is a book about taxonomy for taxonomists", while the subtitle of the book claims that it is both a text and a work of reference.

Presenting the intricacies of taxonomy at length to satisfy so diverse a public and to fulfil such diversity of need is a near impossible task and it is not surprising that the attempt has resulted in a relatively expensive work not fully suited to the student purse or mind, or to the taxonomist. This is a pity, for there is a need for a comprehensive book on this subject that would encourage students with a leaning toward taxonomy to enter this field—Dr Blackwelder's book might achieve the reverse. Nevertheless, it contains a very great deal of information not easy to find elsewhere and much opinion and advice arising from his long experience as a leading taxonomist that others will wish to note. For a subject which is heavily determined by its history, however, it is surprising that the historical component receives scant attention in a couple of pages or so of the introduction. In consequence it is not always clear why things are now done the way they are and much of the sense of continuity of taxonomy through time is lost.

It is not easy to follow the theme of this book, for it can be opened and read almost anywhere (albeit with profit) and it does not seem to matter very much what has gone before or what comes after. Moreover, the text is badly interrupted by lists such as universities of the United States offering courses in taxonomy, societies concerned with taxonomy, and museums, which could have been relegated to an appendix. The student thus gains little sense of order and no stimulus to read further, and for this reason the book is unsatisfactory as a student text.

J. E. Webb

SEAWEED POLYSACCHARIDES

Chemistry and Enzymology of Marine Algal Polysaccharides

By Elizabeth Percival and Richard H. McDowell. Pp. xii+219. (London: Academic Press, Inc. (London), Ltd.; New York: Academic Press, Inc., 1967.) 60s.; \$12.

THE general nature of the polysaccharides of seaweeds, forming in the main the cell walls and storage products,

has been known for a long time. Algal starches have long been known, for example, to be very much the same substances as the starches of higher plants and the cell walls of many algae have been known to resemble those of higher plants in being based on cellulose associated with a wide variety of non- or para-crystalline polysaccharides based on sugars other than glucose. During the past decade or so a number of workers in various parts of the world have turned their attention to detailed chemical examination of algal polysaccharides, and this book, written by two authors of whom the senior author particularly is an outstanding authority, presents a comprehensive account of the present state of this study. The stimulus for this sudden expansion in our knowledge of marine algal polysaccharides undoubtedly springs from two sources: the increasing commercial utilization of these products of algal metabolism and an increasing tendency among plant physiologists to use the simpler algae as model systems as an aid to an understanding of higher plants. This book is unavoidable reading from either point of view. It does not pretend to deal exhaustively with many of the topics covered, but the reader is directed copiously to the relevant original literature listed at the end of each chapter. This makes it an easily read book, manageable in size, and yet an almost complete guide into all the current and immediate past literature of importance. It assumes in the reader some previous knowledge of organic and physical chemistry but this is offset to some extent by the second chapter in which detailed coverage is given of the modern methods of chemical structure determination with polysaccharides.

After a preliminary survey in the first chapter and the methodology of the following chapter, six chapters deal in turn with food storage, food reserve and structural polysaccharides, with alginic acid, sulphated polysaccharides and polysaccharides containing uronic acid and ester sulphate groups. A useful last chapter compares algal polysaccharides with both higher plant and animal polysaccharides.

This is a very useful and timely book. It is well presented, with a subject and author index, and I detected exceptionally few printing errors, none of them misleading. It is strongly recommended reading not only for phycologists but for plant physiologists in general and for all those involved in commercial exploitation of seaweeds.

R. D. Preston

AQUATIC MICRO-ORGANISMS

Microbiology of Oceans and Estuaries

By E. J. Ferguson Wood. (Elsevier Oceanography Series.) Pp.xi+319. (Amsterdam, London and New York: Elsevier Publishing Company, 1967.) 135s.

THERE is undoubtedly a need for a good textbook on marine and estuarine microbiology. The range of topics covered by Professor Wood in his recent book, *Microbiology of Oceans and Estuaries*, is well chosen and his writing is lucid. It is questionable whether the book will serve as a useful textbook, for it falls between two fires, being too general for the specialist and far too discursive for the beginner.

Many chapters and sections are welcome and well written; in particular are those dealing with microbial symbioses, fouling, corrosion, fish spoilage and geomicro-They bring together under one cover a wide variety of information together with many of the personal observations and findings of the author. The parts of the book describing the inter-relationships between pH, redox potential and various chemical, biological and geobiological events are generally interesting and useful. The description of the bacterial groups in the chapter on bacteria and fungi is clear and easily understood and will probably be useful to the student. In sharp contrast, his description of the phytoplankton groups is poor. text of the section on the dinoflagellates is very difficult to understand and the accompanying illustrations give little help. In this chapter species and genera are referred to and even discussed at length, without their features being described to the reader. A person with limited prior knowledge of phytoplankton will gain little from this chapter. The quantitative aspect of marine production is given very curt treatment and the author's personal views on the subject are made very plain.

In summary, the book lacks the orderly presentation of information expected of a textbook and leans rather heavily on the personal observations and opinions of the author. In all fairness to Professor Wood it should be said that it is not easy to write a book on aquatic microbiology and probably impossible to write a good one. The price of the book is surprisingly high considering its size and that it is not lavishly illustrated.

P. J. LE B. WILLIAMS

Physical Science

NEW WAYS WITH ATOMIC LEVELS

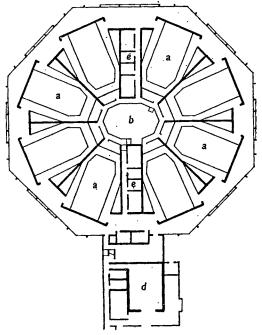

Second Quantization and Atomic Spectroscopy (G. H. Dieke Memorial Lectures.) By Brian R. Judd. Pp. viii+61. (Baltimore, Md.: The Johns Hopkins Press; London: Oxford University Press, 1967.) \$5.95; 48s. net.

This little book is concerned with a different approach from the usual to the question of atomic energy levels. The usual method is to construct a suitable electronic wave function to represent the most important part of the complete wave function, and then to mix in with it wave functions for other "excited" configurations. The analysis is heavy, as anyone will soon admit who has struggled with the appropriate wave functions for rare earth configurations based on f^n . Professor Judd shows that the systematic use of creation and annihilation

operators can greatly reduce the labour. Moreover, because one configuration can be found from another (the basic one) by annihilating one electron and creating another in a different orbital, there is no need actually to set out explicit forms for these other configurational wave functions. The techniques of second quantization have not often been used in this way, but they throw light on the Racah formalism of fractional parentage, and are easily visualized in terms of Feynman-type graphs.

The present book is described as the lecture notes for a series of lectures at the Johns Hopkins University. The eight chapters are clearly set out, though they would be easier to read if they had been a little more extensive. They represent a significant advance in this field. Their only major defect—which rubs them out from all but libraries—is their cost. Forty-eight shillings for fifty-five pages and an index is ridiculous. C. A. Coulson

WHERE TO TEACH SCIENCE

Plan for a classroom and studio building of the University of Miami, Florida. a, Auditoria, each seating three hundred people. b, Back projection area. From The Science Lecture Room, by Jeremy Taylor (Cambridge University Press; 60s.). The book is a planning study which examines the principles of location and design of lecture rooms in the development of university science areas.

LIQUID AND SOLID HELIUM

The Properties of Liquid and Solid Helium By J. Wilks. (The International Series of Monographs on Physics.) Pp. xii+703. (Oxford: Clarendon Press; London: Oxford University Press, 1967.) 150s. net.

THE torrent of scientific papers is such that physicists would be carried away beyond rescue but for the work of those few of their devoted colleagues who, by pausing from time to time to embody their learning in monograph form, construct a series of rocks on which the rest of us may clamber from the flood and attempt to renew our perspectives for a while before diving in again. The first liquid helium rapids of the late 1930s were stemmed in 1942 by Keesom's celebrated work, Helium, from which a whole conspectus of helium, solid, liquid, gascous, atomic, nuclear, scientific, historic and technical, could be taken. The waters continued to rise, with the additional hazard that some navigation in Russian was called for, until Atkins in 1959 regained control of some tributaries by his book Liquid Helium. Now, twenty-five years after Keesom's book, comes Dr Wilks's The Properties of Liquid and Solid Helium.

This work will command not only respect but also gratitude from all those who have fallen under the fascination of the condensed states of helium; the respect will be shown to the author's authority, and the gratitude to the clarity with which he treats both experiment and theory. His lucid style is supported by the excellent printing and diagrams typical of the Clarendon Press. Roughly two-thirds of the book is devoted to liquid helium four, one sixth to liquid helium three, and the remaining sixth to the solid phases. As is proper, the author's particular interest in zero sound is allowed to detain us a little when we read about helium three.

One of the conspicuous features of the book is the gathering together and presentation of introductory

material necessary for an understanding of the theory. Thus the author takes care that the requisite ideas of fluid mechanics, statistical mechanics and quantum mechanics are explicitly laid out ready for use. He also offers a quite invaluable chapter on phonons in crystalline solids, by way of introduction to the excitation theory of liquid helium II.

It is only to be hoped that the rather high price of this book will not prevent it from being available to the many scientists to whom it has so much to offer.

D. V. OSBORNE

RELATIVITY AND SOLUTIONS

Relativistic Hydrodynamics and Magnetohydrodynamics Lectures on the Existence of Solutions. By Andre Lichnerowicz. (The Mathematical Physics Monograph Series.) Pp. ix+196. (New York: W. A. Benjamin, Inc., 1967.) \$9.50.

This book is addressed to a restricted audience; it is concerned with the mathematical study of the equations of relativistic hydrodynamics. Its origin lies in a course of lectures given to graduate students at the Centre of Advanced Study in Dallas at the end of 1965. The book is, in essence, the reproduction of a set of mathematical lecture notes with an almost complete absence of physical interpretation.

Familiarity with relativistic hydrodynamics is assumed and this involves a working knowledge of relativity, hydrodynamics and the theory of partial differential equations.

In a fluid which is hydro- and thermo-dynamically perfect the treatment yields three systems, gravitational waves, hydrodynamic waves and stream lines, and the problem is extended by introducing an electromagnetic field and a fluid which is charged but has a vanishing electrical conductivity. The more difficult case of relativistic magnetohydrodynamics assumes inductive effects on a perfect and infinitely conducting fluid. This leads to Alfven, hydrodynamic and relativistic shock waves.

JOHN PAIN

MASS SPECTROMETRY

Mass Spectrometry of Organic Compounds

By Herbert Budzikiewicz, Carl Djerassi and Dudley H. Williams. (Holden-Day Series in Physical Techniques in Chemistry.) Pp. xv+690. (San Francisco and London: Holden-Day, Inc., 1967.) \$19.75.

This is both a very valuable and an interesting book, for several reasons. The coverage of the organic compounds discussed is very wide, comprising most simple classes of materials possessing functional groups, including the alcohols, aldehydes and ketones, ethers and other oxygen-containing molecules; their sulphur analogues; amines, amides, cyanides and other nitrogenous systems; halides, as well as the parent hydrocarbons; organic phosphorus compounds and even a comprehensive, if brief, account of organo-metallic systems.

Moreover, this book is written from a distinct point of view which is clearly stated at the outset (page 9, first paragraph et seq.); namely, that of charge localization. This is an important unifying concept which is currently of considerable interest. The views of these authors with whom this theory is already associated as a consequence of an earlier work (Interpretation of Mass Spectra of Organic Compounds) are most timely, although the simplicity of the idea is somewhat eroded by specific compounds, notably among oxygen-containing molecules (for example, page 100, line 6; page 133, line 9; page 180, fourth paragraph).

Further, the scale of this book and the speed at which it was achieved are a remarkable tribute to the authors. There seem to be a few errors which are mainly trivial. Those noticed by the reviewer tend to occur towards the end and are more irritating than serious. These include two misspellings, phosphorus (page 648, line 27) and Tabrizi (page 668, ref. 12), and an unfulfilled promise of cross references (page 612, lines 2 and 3).

In a book of this character what is included and omitted must be at the discretion of the authors, although I regret that some guidance was not afforded to future imitators, advising which ions should be considered for the discussion of an unknown structure and which may be discarded as inessential.

A particular criticism which may be made is that in considering "electron book-keeping" (page 1, line 14), the claims of R. M. Silverstein and G. C. Bassler (Spectrometric Identification of Organic Compounds, John Wiley and Sons, Inc., New York, 1963, page 8, column 1—author's note) to have originated this idea should have been overlooked.

Finally, the publishers are to be congratulated on the production of a book of such quality. The format is pleasant, the text legible, and the numerous line diagrams well produced; as indeed are the graphic formulae so often a stumbling block in the production of chemical texts.

Altogether a book to be recommended to those interested in the subject and a must for workers in this field.

ROWLAND I. REED

ORGANIC POLAROGRAPHY

Substituent Effects in Organic Polarography By Petr Zuman. Pp. xvi+384. (New York: Plenum Press, 1967.) \$17.50.

THERE is a tendency to assume that, as far as polarography in organic chemistry is concerned, the method is no more than an analytical tool. Further, because the present writer is the author of a very well known volume entitled Organic Polarographic Analysis, it might be casually assumed that the volume being reviewed is merely an extension of the analytical applications of polarography in organic chemistry. Such assumptions would, however, be far from the truth for, in this monograph, Dr Zuman presents an original attempt to meet a real need, that is, to provide a systematic relationship between the polarographic behaviour of organic substances and their structure.

Experimental evidence is summarized which shows that polarographic data can be treated by the use of coefficients which characterize the effects of substituents quantitatively, giving a clear understanding of structural effects on half-wave potentials.

The book contains ten chapters, beginning with one on the development of the study of structural relations, classification of and techniques used in the polarographic study of structural effects, which should be read by all physical organic chemists.

To establish a correlation between reducibility and structure, a general equation for the shift in half-wave potential caused by substituent effects is derived in the second chapter, which takes into account, among others, conditions for the application of the general equation. In the following chapters, the possibility of application of special forms of the general equation to benzene derivatives, monocyclic compounds, and alicyclic systems, to name only a few, is demonstrated.

Zuman claims that he has two principal aims. The first is to show the organic polarographer the types of problems which can be treated quantitatively: the second is to show physical organic chemists what polarography offers for the solution of fundamental problems. Both aims have been achieved admirably in a very interesting book.

R. J. MAGEE

SYMPOSIUM ON TITANIUM

Titanium and its Alloys

Edited by I. I. Kornilov. (Publication No. 10: Investigation of Titanium Alloys.) Translated from the Russian. Pp. vi+386. (Jerusalem: Israel Program for Scientific Translations; London: Oldbourne Press, 1966.) 117s.

THE book presents the translations of the papers delivered at the Second Conference on the Theoretical and Experimental Investigation of Titanium Alloys which was held at Baikov in March 1962. The papers are divided into three groups under the headings "Reaction of Titanium with Other Metals and the Structure of Titanium Alloys" (thirteen papers), "Interaction of Titanium with Gases and Corrosion Properties of Titanium Alloys" (eleven papers) and "Mechanical and Technological Properties of Titanium Alloys" (twenty-three papers).

The first group of papers opens with a review of the crystal structures and the electronic structure of titanium and its alloying behaviour and, on the basis of these data, seeks to develop an alloy theory for titanium. Several papers on phase equilibria in titanium alloys follow. Partial phase diagrams, variously determined by metallographic studies, X-ray diffraction, electrical resistivity and hardness measurements, are presented for the systems titanium-aluminium, titanium-aluminium-molybdenum, titanium-niobium-chromium and titanium-vanadiumniobium-molybdenum, using alloys prepared from iodide titanium (that is, high purity material) and for the systems titanium-aluminium-chromium-iron-silicon and titanium-aluminium-chromium-iron-silicon-boron, using alloys prepared from commercially produced sponge titanium. Particular attention is paid to certain sections through the last system, because these sections form the constitutional basis for the Russians' AT series of commercial alloys. The paper on the titanium-aluminium system contains a critical review of earlier work on this controversial diagram and presents a new version of the diagram. Despite this revision of the diagram, the papers on the polycomponent systems containing aluminium all assume the simple form of the diagram that was proposed initially. One paper presents data on the crystal structures of ternary intermetallic titanium compounds containing a transition element and an element belonging to one of the groups IIIB, IVB or VB of the periodic table. A systematic variation in structure with the group of the third element is demonstrated. Finally, a paper is devoted to the use of a high vacuum dilatometer, to the study of phase changes in titanium and to the cyclic sintering of isostatically compacted titanium.

Despite the fact that the second group of papers is devoted to the interaction of gases with titanium and the corrosion properties of titanium and its alloys, four other papers on these topics are to be found in the third group of papers: these are considered with those in the second group. Altogether, six papers deal with the elevated temperature oxidation of titanium and certain of its alloys. In all cases, formation of scale and oxygen contaminated layers at the surface was observed and the papers record studies of the kinetics of the oxidation processes, the nature of the scales formed and the influence of the gas contaminated surface layer on room temperature mechanical properties. Two papers are devoted to aspects of hydrogen in titanium and its alloys: one to a study of the evolution of hydrogen from metal heated in vacuum and the second to a study of its influence in producing delayed cracking and embrittlement at low temperatures. Five papers on corrosion report the behaviour of titanium and some of its alloys in various corrosive media, including some encountered in the chemical, the pharmaceutical and the food industries, while a single paper reports the tendency of certain alloys to corrosion and stress-corrosion in synthetic industrial media.

The final group of papers deals with a variety of topics,

including the effects of structure and composition on the elastic moduli of titanium alloys, the effects of composition, cold working, annealing and heat treatment on room temperature mechanical properties of both laboratory prepared and commercially produced titanium alloys, stress-rupture characteristics (described throughout the book as "heat resistance"), creep and thermal stability of various alloys, assessment of the suitability of certain alloys for cold rolling and tube production and aspects of the welding, brazing and soldering of the metal and its alloys. The absence of any work on fatigue behaviour is noteworthy.

Finally, the book concludes with a brief summary of the recommendations of the conference with respect to future investigations of titanium alloys and the coordination of such work between research institutes and industry.

Most of the papers are written in a concise manner. The references to earlier work show a surprising familiarity with papers published in the West. Most papers are of the type produced during the development and evaluation of alloys and are largely factual in character and practical in outlook. In the West, this type of work is usually carried out by private companies which treat the results as confidential and, consequently, such work rarely finds its way into scientific and professional journals. Thus, this book is likely to be of most interest to metallurgists and others employed in the development and evaluation of titanium and its alloys. Metallurgical students, however, may find the book of some interest, not for the detailed contents of the papers, but for the insight that can be gained into the type and volume of work involved in the development of alloys-information which is not readily available elsewhere. Following through the many papers dealing with the AT series of alloys from their phase equilibria to the evaluation of their mechanical behaviour could be an instructive exercise.

A serious omission which detracts appreciably from the value of many papers is the failure to give the analyses of the alloys used in the investigations. Furthermore, in a number of papers alloys are referred to only by their technical designations, the specifications for which are not given in the book. In many instances, typical compositions of alloys may be found by reference to other papers in the book, although in a few instances this procedure fails to yield the desired information. The serious reader would do well to equip himself with the list of compositions corresponding to the various specifications before embarking on a study of the papers.

fications before embarking on a study of the papers.

In general, the quality of the translation of the papers that are largely factual in character is good. The quality of translation of the few papers that are discursive in character is less good and in places they are difficult to follow. More careful editing could have avoided this situation. A few persistent misleading mistranslations occur throughout the book: iodide titanium invariably is described as titanium iodide and melting as smelting. The text and line drawings are printed clearly and the photomicrographs and other half-tone diagrams, on the whole, have reproduced well.

R. Haynes

NIOBIUM AND TANTALUM

The Chemistry of Niobium and Tantalum By F. Fairbrother. (Topics in Inorganic and General Chemistry, Monograph 10.) Pp. viii + 243. (Amsterdam, London and New York: Elsevier Publishing Company, 1967.) 105s.

THIS book contains a wide ranging and up to date appraisal of knowledge of the chemistry of these two metals. In all, 688 references are cited, some as late as mid-1966, but the author has succeeded in presenting a

vast amount of information in a clear, concise, and readable way throughout the book. Full experimental details are omitted and the chemistries of the two elements are described side by side following the precedent set in earlier monographs.

After a short introduction, the author presents a chemist's account of the separation, extraction metallurgy and physical properties of the elements. This is followed by a detailed treatment of compounds of the elements with oxygen, the halogens, hydrogen, carbon, silicon, boron, the elements of group VB, and the remaining chalcogens. The clarity of description in the section on anhydrous binary halides is particularly illuminating. A comprehensive survey of methods available for quantitative analysis of the elements comprises the final chapter and the book ends with a good subject index.

Most of the numerical data on niobium and tantalum compounds have been obtained from X-ray measurements and studies of phase equilibria. The author has assiduously collated and presented these data in numerous tables, making the text a valuable source-book for X-ray workers in the field. Spectroscopists interested in longer wavelengths are referred to the original papers: this is disappointing in view of the small but growing body of information on electronic, infrared and nuclear magnetic resonance spectroscopy, which has been contributed to by theoretical chemists as well as by preparative chemists. Undergraduates and newcomers to the field should, however, have little trouble in grasping a clear picture of the chemistry of the elements from this monograph.

The book contains no important printing errors and is satisfactorily bound. It is distressing to note that the monograph is the most expensive in terms of price per page as well as the most recent in the series, but for libraries and specialists this book is a must.

PILLARS OF WISDOM?

Seven Solid States

An Introduction to the Chemistry and Physics of Solids. By Walter J. Moore. (The General Chemistry Monograph) (New York and Amsterdam: Series.) Pp. xii + 224. W. A. Benjamin, Inc., 1967.) \$7 cloth; \$2.95 paperback. This short book provides an introduction to solid state physics and chemistry with undergraduate chemists in mind as the most likely readers. Its approach is attractive and original. Seven specific substances (salt, gold, silicon, steel, nickel oxide, ruby and anthracene) are described. one in each of the seven chapters, and their properties used as illustrations of general topics in the solid state. For instance, the chapter on common salt contains an introduction to crystal structure, X-ray diffraction and lattice vibrations. The chapter on gold includes a general discussion of the properties of electrons in metals, and the chapter on ruby outlines the behaviour of transition metal ions in the presence of crystalline electric and magnetic fields. One or two sections seem especially valuable. For example, there is a very useful simple description of the iron-carbon alloy phase diagram in the chapter on steel. which is not easy to find elsewhere. The chapter on silicon contains an adequate basic description of semiconductor properties, the p-n junction and transistor mechanism. There are several useful sections on crystal growing methods, and the chapter on ruby contains a good introduction to the principles of electron spin resonance and maser action.

A great many topics are dealt with in two hundred pages and the treatment is, in many cases, inevitably lacking in depth. Discussion of some material—for example, specific heats of solids—is so brief as to lack plausibility. One is disappointed to find the description of magnetically ordered systems restricted to only three

pages of text. The book is well produced and the diagrams and photographs are particularly attractive. The style is informal and non-mathematical.

As a first introduction to the subject, this book is likely to appeal much more to chemistry than to physics students. The manner in which the solid state is taught in physics departments implies the use of a book in which a more restricted range of topics is treated in greater detail, and in which use can be made of a basic knowledge of thermodynamics, statistical mechanics, and quantum mechanics, which the student will, one hopes, have acquired at an earlier stage. R. E. MEADS

PHOTOCHEMISTRY CONFERENCE

Reactivity of the Photoexcited Organic Molecule (Proceedings of the Thirteenth Conference on Chemistry at the University of Brussels, October 1965.) Pp. ix + 350. (London and New York: Interscience Publishers, a Division of John Wiley and Sons, 1967.) 126s.

It is a pity that this good book is a "conference proceedings". As such, despite the useful and valuable information it contains, the book will be neglected. It will be misplaced in the library, in that it will not be among the current literature; it will be difficult to refer to and it will be tedious to write out the references to the articles which it contains.

This seems to be the fate of all conference proceedings now, with the exception of those published in the normal literature such as Discussions of the Faraday Society. By being produced sometimes under the name of an editor and sometimes not, they inevitably seem to be filed in the wrong places. Quoting articles from them in papers or in reviews is always difficult: for anyone who does not agree, I suggest that they write out for themselves a short form reference of the article contained in this volume by G. Porter on page 79, working from the full reference to the book shown above. I suggest there will be as many versions as people attempting the problem and many of them will be ambiguous and lengthy. A further point is the price of this book, which is high; the publishers seem to know that it will not be seen by too many people.

One solution to the problem would be for the publishers to obtain contracts in the usual way, but to combine together perhaps with the aid of a learned society to produce series of conferences proceedings in, say, physical chemistry, organic chemistry, fluid dynamics, etc. These, while still being produced by various publishers, would be assigned a volume number by agreement so that for example "Conference Proceedings in Physical Chemistry" formed a sensible series. Then one might refer to the article mentioned above as say G. Porter, Conf. Proc. Org. Chem., Volume 000 (1967), page 79. In this way our librarians would both wish to obtain them and know where to file them; they would be easy to reference. The greater circulation would allow the price to be lower and people would be encouraged to buy individual volumes on topics which interest them.

Once again, this is a good book. There are a series of reports by distinguished workers: Coulson, Daudel, Porter, Hammond, Yang, Dauben, Havinga and Schmidt. These range from the theoretical aspects of the subject through reactivity and energy transfer to reports on the organic photochemistry of selected fields including the solid state. Each forms a useful review and in some cases would make a good introduction to the subject for a new graduate student, or someone interested in seeing what organic photochemists are up to. Following each report there is a discussion: as is the custom of the Solvay conferences all the contributors are notable and the questions are to the point.

There are no real deficiencies in the book: it would have been interesting to read the paper by Schenck which is not published but for which the discussion is printed. It is mildly frustrating to find that the French contributors still retain the language of diplomacy rather than using the language of science as everyone else does.

In short, this is a delicious mixture of primer and review, in which the flavour of the field can be tasted. For this reason I am anxious that it should not disappear from sight in the usual way of conference proceedings.

Peter Borrell

CHEMISTRY OF OCEANS

Equilibrium Concepts in Natural Water Systems (Advances in Chemistry Series, No. 67.) Pp. viii + 344. (Washington, D.C.: American Chemical Society, 1967.)

This book, containing the sixteen papers given at an interdisciplinary symposium on the geochemical development of the Earth's natural waters, illustrates clearly the difficulties both of geochemistry and of interdisciplinary symposia. It emerges with credit, but not distinction, from both encounters.

Studies of heterogeneous equilibria involving oxides, carbonates and silicates in aqueous media (of which several accounts are given here) are often impeded by the slowness with which equilibrium is approached. Moreover, an additional degree of freedom is available to colloidal systems in which surface energies contribute significantly to the total Gibbs free energy. In the organic field, the problems are no less severe: photosynthesis causes the accumulation of thermodynamically unstable carbon compounds which may persist for geological timespans. Complications of a higher order are introduced by the possibilities of biological mediation in many other chemical processes.

It is therefore scarcely surprising (despite the title of the volume) that several authors should express careful reservations concerning the relevance of equilibrium thermodynamics to studies of natural water systems. It is hoped, however, that progress can be made by comparing natural systems with calculated equilibrium states of suitable models (or steady states if open-system models are used). This approach acquired much impetus from the pioneering work of L. G. Sillén, who contributes to this volume an account of a clarified method of representing complex equilibria, and illustrates impressively its value in an application of Gibbs' phase rule to a geochemical balance in an eight component ocean model. Other contributions are largely directed towards the provision of basic data for such studies, and outlining the difficulties besetting their interpretation. Two examples are given of successful comparisons between real systems and appropriate models.

Participants at interdisciplinary conferences are menaced by the danger of mutual unintelligibility. This has been admirably overcome in the present instance, for the contributors have evidently been encouraged to remain within a fairly narrow geochemical context. At the other extreme, such a limitation could detract from the value of interdisciplinary exchanges, transforming what should be exciting adventures in cross-fertilization into a kind of scientific incest. This danger has also been avoided, although more narrowly: one might have expected more scope for controversy to be evident in a developing subject

of such complexity.

This book is clearly intended to stimulate further research: its success will be measured by the brevity of its life-span. Its value as an instantaneous picture of current research would have been enhanced by the incorporation of an editorial epilogue synthesizing the various views expressed.

There is an irritating abundance of minor typographical J. M. HAYNES

Applied Science

STATISTICS HANDBOOK

Handbook of Methods of Applied Statistics

By I. M. Chakravarti, R. G. Laha and J. Roy. Vol. 1: Techniques of Computation, Descriptive Methods, and Statistical Inference. Pp. xiv+460. 98s. Vol. 2: Planning of Surveys and Experiments. Pp. x+160. 68s. (Wiley Series in Probability and Mathematical Statistics.) (New York and London: John Wiley and Sons, 1967.)

In the preface to this handbook, the latest addition to the justly famous Wiley series, the authors state their aim—"to bring together under one title most of the essential techniques of quantitative inference"—and describe their method of achieving this aim—"In each part, every basic statistical method is described in detail with a precise explanation of its theoretical foundation. Then the computational procedure is discussed and illustrated by numerical examples completely worked out. These are followed by a large collection of selected and graded exercises". These are ambitious claims and in the main they are well realized.

This pattern of theoretical discussion, description of method and worked example enables the authors to be very informative about an immense range of topics, some of which require considerable sophistication on the part of the reader. Practically every basic statistical technique is thus presented, the only notable omissions being decision theory methods and spectrum analysis, although some topics such as the method of steepest ascent and quality control and sampling inspection schemes receive a more brief treatment. The organization of the material permits easy reference to particular topics, although bold faced type in place of italics for subsection headings would have facilitated this still more. Except in the second part of the first volume, the theoretical discussions are informative and sound and the methods suggested are varied and appropriate. By and large, one can only complain of relatively trivial errors of omission. Throughout the second part of the first volume, however, population and sample are confused both in the text and in the notation, a fault that in a work of less overall value would in my opinion damn the work completely. Fortunately, the third part, on statistical inference, appears to have been written by a different member of the team of authors and there, for the reader who gets that far, the misconceptions of the second part will be corrected.

The extensive collections of exercises are built on real data and indicate strikingly the many branches of science and technology in which statistical methods are applied. Unfortunately no solutions appear to be available. There are a few proof-reading errors, most of them obvious, although in the first volume the failure to use the bold-faced 'e' for the unit vector on page 412 makes possible its confusion with 'e' which is the number of degrees of freedom on page 417, and there is some misprint in the definition of convergence in probability on page 256. The index is, for a reference work of this type, only just adequate. No tables are given but references are given for most of the standard tables. References at the ends of chapters to books in which could be found formal proofs of the points made in the theoretical discussions would have been a valuable addition to this generally very useful compendium of statistical theory and method.

Despite these minor points and the more serious confusion in the second part, this handbook is a worthy

addition to the Wiley series and a pleasant reminder of the flair for statistics so frequently displayed by Indians.

M. E. Solari

LASER INFORMATION

Laser Systems and Applications

By H. A. Elion, with a foreword by T. H. Maiman. Pp. xi+624. (Oxford, London and New York: Pergamon Press, Ltd., 1967.) 147s. net.

Of the 624 pages in this book, 353 are devoted to a NASA special bibliography on lasers classified by subject matter and authors. Only the NASA accession numbers are given and no reference is made to the open literature. Presumably the buyer is paying nearly four guineas for this bibliography. This scarcely seems a good buy even for readers who have easy access to the eleven Federal Regional Technical Report Centres listed on page 607. More useful bibliographies are regularly published in the Journal of the Optical Society of America and the IEEE Journal of Quantum Electronics.

A further fifty pages are devoted to appendix 2 describing simple experiments in physical optics using gas laser beams. While this appendix would be a very useful guide for introducing gas lasers into sixth form teaching laboratories, it seems somewhat out of place in the present volume.

The remainder of the book is a readable, well illustrated account of the state of the art of applying lasers to a variety of problems. These include welding and machining; chemical and biological applications; holography and spectroscopy; ranging, surveying and metrology; communications and optical data processing and display. Little demand is made on specialized technical knowledge and mathematical formulae are kept to a minimum.

The notes on health hazards are sensible if brief. The tables of physical constants and characteristics of various types of lasers contain by far the most useful information in the book.

D. J. Bradley

COMPUTERS ADVANCE

Advances in Computers

Vol. 8. By Franz L. Alt and Morris Rubinoff. Pp. xii + 345. (New York: Academic Press, Inc.; London: Academic Press, Inc. (London), Ltd., 1967.) 116s.

Advances in Computers has now reached the eighth volume. Over the years, the editors have given us a series of timely and authoritative articles on subjects of current interest in the computer field. This volume lives well up to the standard that has been set in the past.

standard that has been set in the past.

The first article, by Thomas N. Pyke, of the National Bureau of Standards, is on time-shared computer systems. The author defines time sharing as the simultaneous access to a computer system by a number of independent users. Pyke has obviously been in a position to follow closely the developments he describes, and the article can be strongly recommended to experts and non-experts alike.

Jean E. Sammet of IBM writes on formula manipulation by computer. She gives a good summary of the various systems that have been developed for doing algebraic manipulation of a formal kind (including dif-

ferentiation and integration) on a computer. A bias towards FORMAC may be forgiven her.

Tom Steel of the System Development Corporation complains, in an article on standards for computers and information processing, that this topic is apt to induce disinterest, boredom and apathy in the reader. He might have added active opposition (have we not heard it said that standardization is not putting right the last fellow's mistakes?). Steel seeks to arouse at least a fleeting fascination for the subject by sketching the history of standardization and its influence on society. He goes on to describe the way in which United States standards are evolved and the various agencies that are concerned. The topic to which he gives most attention is that of standardization of programming languages, a field which he is too modest to point out owes a good deal to his personal efforts.

Dr Naomi Sager of the Institute for Computer Research in the Humanities of New York University contributes an article on the syntactic analysis of natural language. She discusses various methods for grammatical analysis of sentences and gives an example of her own approach to

the problem.

The two final papers are more in the nature of research contributions than expository articles. R. Narasimhan of the Tata Institute of Fundamental Research in Bombay presents a unified metatheory of programming languages and computers. This is a theory of the way in which programming languages may be described, and these turn out to be the same as the ways in which computers themselves can be described. The last paper is by L. A. Lombardi of the University of Rome, and is entitled "Incremental Computation". Lombardi outlines a language which accepts problems whose formulation is still incomplete and for which additional information is supplied in instalments. This paper is to be viewed as a contribution to the new type of thinking that is becoming necessary now that we are beginning to achieve what Licklider (quoted by Pyke in the first article in the volume) has termed mancomputer symbiosis. M. V. WILKES

POLISHING METALS

Metallographic Polishing by Mechanical Methods By L. E. Samuels. (Metallography Series.) Pp. x+195. (London and Melbourne: Sir Isaac Pitman and Sons, Ltd., 1967.) 70s. net.

METALLOGRAPHY is concerned with those crystalline features that manifest themselves in metals at microscopical level, and their significance in respect of the ultimate metallic properties. Conventional metallography primarily utilizes the optical microscope, using the greater resolving power of the electron microscope as a supplement to elucidate where appropriate the finer details of structure.

Metallographic examination of a metal involves, on one hand, the proper preparation of the samples and, on the other, their critical examination under the microscope. Clearly, the success of the latter depends to a large extent on the efficiency of the preparation stage. In recent metallography, two names stand out as having made distinctive contributions to the techniques of preparation. The first is that of the late P. A. Jacquet and the other is that of the author of the present book.

L. E. Samuels cannot aspire to such eminence as Jacquet, who made such unique contributions to electrolytic polishing. Mechanical polishing in one form or another has been with us ever since the science of metallography evolved. Even diamond polishing, with which Samuels's name is associated, was first used by a number of other workers. Samuels's claim to fame is that, from specialized applications, he introduced diamond polishing as the universal technique and, indeed, he took most of the art out of mechanical polishing for optical micro-

scopy. He pioneered the use of a paste carrier rather than a liquid. He studied the variables, and described the optimum conditions. Moreover, he developed confidence both by the superb results obtained in his own work, and by analysing the behaviour of the underlying metal surface during the polishing action. These results have been described in a series of useful papers, but it is fitting and beneficial that he should now incorporate much of his experience into a book.

It might at first be doubted whether the subject of mechanical polishing justifies a book on its own account. Examination of the contents of this volume, however, will soon dispel such doubt, although in my opinion the work would have been better and of wider value had it incorporated at least a general introductory account of etching.

The author deals with sectioning, machining and abrasion, with mounting of specimens, and with their polishing, including the use of fine oxide powders for post-diamond finishing. He analyses the fundamental principles as well as describing the actual practice. Very detailed or subsidiary aspects of preparation are dealt with in a number of appendices. These include such useful items as the manufacture of a conducting plastic, special lap materials, levigation of alumina, diamond paste preparation, factors controlling the resonance of an electromagnetic vibratory polisher, and electroplating methods for edge protection of specimens. In addition, there is a valuable chapter comparing electrolytic with mechanical polishing. The text is illustrated throughout by excellent photomicrographs selected largely from the author's own investigations.

In all, this is a good book, clearly written by an expert, and it will be of great value to all concerned with metallography.

A. R. Bailey

WORK AND HEAT

Engineering Thermodynamics

Work and Heat Transfer (SI Units). By G. F. C. Rogers and Y. R. Mayhew. Second edition. Pp. xii + 662. (London: Longmans, Green and Co., Ltd., 1967.) 60s. net.

The new edition, in SI units, follows the same successful layout as the first edition in Btu. The primary need for this new edition springs from the declared national policy of changing to the metric system. The authors have gone all the way and chosen what is known as a coherent system. That is to say, they have abandoned the general relationship p=kma in favour of the specific relationship p=ma. The fundamental units used are kilogramme, metre, and second, for mass, length, and time, with a derived unit kg.m/s² or newton for force. This is the system that will generally be used in scientific work and one can only hope that industry will follow suit.

The book contains all that was best in the first edition. but the authors have brought the work more up to date by some additions. They have, for instance, introduced the concept of availability in closed and open systems. Also, they have gone further than previously in their discussion of the use of the Gibbs function. Latent enthalpies of fusion and of evaporation are studied in greater detail.

The authors, in the new edition, discuss briefly some of the consequences arising from the application of nuclear energy sources to steam cycles, such as restrictions on the maximum permissible temperature that fuel elements are allowed to reach, and from the uses of a secondary fluid to transfer energy from the elements to the steam.

Combustion theory has been newly set in its correct light and is shown to be a particular class of chemical reactions in general. Into the chapters dealing with the internal combustion engine the Wankel engine has been introduced with illustrations and adequate description. A whole new chapter on direct conversion covers thermionic and

thermoelectric converters, magnetohydrodynamic generators and fuel cells.

In the chapters on heat transfer, the conduction section has been enlarged, and the convection section deals in much more detail with the mechanics of boiling. All these additions are considerable improvements.

The printing of the new edition appears to be slightly smaller and better in this newest edition; the lines are a little farther apart and the pages larger. The whole effect is pleasing and inviting to the reader. The number of

pages has increased from 559 to 601.

The book is the best general textbook for undergraduates learning thermodynamics to degree level and is a very useful reference book for graduates working in other fields. The authors have struck a relationship between the purely scientific and the practical that seems to suit the engineering academic very well.

Russell Hoyle

JOURNAL FOR MATHEMATICIANS

Journal of Engineering Mathematics

Vol. 1, Number 1 (January 1967). Pp. 86. (Groningen: P. Noordhoff, Ltd., 1967.) Subscription per volume \$16.50, postage included.

THE work in applied mathematics in the many outstanding educational and research institutions in the Netherlands is of great importance in both volume and quality, and it is good to see that this work will in future be readily available in a convenient form through the Journal of Engineering Mathematics, being published on a quarterly basis from April 1967 onwards. Although this is almost entirely a Netherlands initiative in respect of publishers, editors and authors of the numbers so far available, papers will be published exclusively in English (preferred). German and French.

It is also good to see the emphasis on application of the mathematics to practical problems in the engineering indus try made both in the journal's title and in the statement of policy on the inside cover, which reads: "The aim of the journal is to promote the application of mathematics to engineering problems and to stress the intrinsic unity of the fundamental problems of different branches of engineering varying from basic principles of physics and mechanics to management and computer science."

These aims are very close to those of the three year old Institute of Mathematics and its Applications in the United Kingdom. In both cases they stem from the need to help the growing body of applied mathematicians in industry and gove.nment (in graduates alone, more than four thousand in the United Kingdom and increasing at 5 per cent per annum), and those in universities and technical colleges, to become more creatively aware of each other's work: especially, it is desirable that the best modern mathematical techniques and principles for applying them be made known to those in industry, and, also, that the researches of those in academic life become closely related to the needs of industry and government, including, of course, their long-term needs.

Journals like the Netherlands Journal of Engineering

Journals like the Netherlands Journal of Engineering Mathematics or the British Journal of the Institute of Mathematics and its Applications can contribute valuably to all this in three ways. First, they can, and should whenever possible, elicit papers from mathematicians working in industry, which will make known characteristic types of mathematical problems with which industry is faced. Secondly, they should encourage applied mathematicians in academic life to submit papers in which the work's practical aims and relevance are clearly set out. Thirdly, they should seek from all appropriate quarters survey papers which will indicate the state of the art in particular (and especially the newer) fields of application of mathematics, or in particular areas of mathematical technique.

There is inevitably a transition while such a journal is getting under way, during which some of the older type of "academic" applied mathematics gets published. Before the journal becomes well known, there are problems of filling up numbers, which militate against rigorous selection from among the papers submitted. Experience with the Journal of the Institute of Mathematics and its Applications shows, however, that provided a substantial number of papers of the right kind are included from the outset, it is increasingly possible, by soliciting both appropriate surveys and also papers from mathematicians in industry and government, to build up a journal that can be more and more of an influence for the creative application of mathematics to the practical problems of industry.

It is evident from the first two numbers of the Journal of Engineering Mathematics, edited by Dr H. W. Hoogstraten of the Technological University of Delft, that the journal will indeed develop along these lines. Problems treated have been chosen not because the mathematics are "elegant", but because they will give the centring force between the rotor and stator coils of an electrical machine at each offset position, or because they will indicate limiting factors on the hydrological performance of water supply systems in one of the Frisian islands, and the results are given in appropriate numerical and graphical detail. There are also good papers from noted Netherlands schools of the mechanics of fluids and of solids.

At the same time, it will in addition be necessary to seek out papers from those who are applying mathematics in industry itself. Wherever possible, it should be made clear, furthermore, that papers from academic institutions should show unambiguously the practical significance of the work submitted. In these conditions, the journal should develop into one of great value to those all over the world engaged in the application of mathematics to the problems of engineering industry.

M. J. LIGHTHILL

OPERATIONS RESEARCH

Introduction to Operations Research

By Frederick S. Hillier and Gerald J. Lieberman. (Holden-Day Series in Industrial Engineering and Management Sciences.) Pp. x+639. (San Francisco and London: Holden-Day, Inc., 1967.) \$13.75.

THE techniques of operations research belong in the main to the mathematical sciences; the practice of these techniques is an experimental science. In some subjects with similar characteristics there is abundant material for laboratory exercises of all grades of difficulty to amplify and illustrate the various stages of the theoretical teaching, and these practical exercises can be presented concurrently with the formal teaching. In fields in which the experimental material is derived from case studies from life the student needs familiarity with, if not mastery of, a sufficient number of techniques to gain full benefit from the practical study. Operations research is predominantly of the latter kind and texts are necessary to present the basic methodology.

Any author of such a text has a wide choice of the amount of mathematical preparation and degree of sophistication he will require of his readers. Professors Hillier and Lieberman have purposely made slight demands in their introductory book; they ask for some familiarity with elementary calculus and for the level of mathematical maturity which usually accompanies such knowledge. In all but a few places (notably in the last section in more advanced topics in mathematical programming) the mathematics is elementary; proofs are often omitted or outlined, there is no insistence on rigour and space is given instead to illustrations of the implications of the results. This approach has much to commend it; the students reading books on operations research are likely to have had little previous contact with the

subject and less experience of it at work. At this stage it is, I believe, more important that the student gains an understanding of the results of the mathematics than that he should be able to derive these results. In the former case, motivation for study of the mathematical details and methods can be established, while in the latter a barrier may be encountered which is never surmounted. A vital part of the understanding of the mathematical results lies in an appreciation of magnitudes when the symbols of the general case give way to the numbers of the particular. Any student can (or should be able to) substitute and evaluate an expression; unfortunately few will do so unless pressed and fewer still will make the immediate approximate calculations which can give the user the "feel" of a formula. The authors do not lose sight of the numerical aspect and many of their examples require calculation as well as algebraic manipulation. Of course, the examples are meant to illustrate the methods; perhaps the numbers are chosen nicely in order to avoid burdening those with less splendid and available automatic computing facilities than at Stanford. Should we not, however, be nearing the time when the embryo scientist can be expected to have a basic knowledge of computer use, ready access to a machine, as well as his grounding in mathematics? When we can assume this—and may it be soon in Britain—the numbers in problems can become realistic and with them the student's approach will become closer to the practitioner's.

Nearly half of the book deals with mathematical programming, introducing some network theory and applications, game theory and dynamic programming, as well as linear, integer and non-linear programming. About the same proportion of the book is devoted to probabilistic models—congestion, inventory, Markov chains and simulation—and a section giving preparation in probability and statistics which can be omitted by those who do not need it. A welcome feature is the repeated questioning whether the model or analysis is appropriate, sometimes with vivid examples (for example, "the result says, for example, that there should only be one rest room, albeit a large one, in the entire Pentagon! So what is wrong with model 3a?"). The mathematics is indubitable and inapplicable.

The book is long; a teacher may have a preference for minor changes in the contents and some will continue to seek satisfactory ways of obtaining and presenting problems in their raw, unformulated state, but the approach to the introductory teaching of operations research techniques will meet with the approval of many.

SOIL, A LIVING TISSUE

Soil Biochemistry

Edited by A. D. McLaren and G. H. Peterson. Pp. xiii+509. (London: Edward Arnold (Publishers), Ltd.; New York: Marcel Dekker, Inc., 1967.) 180s. net.

There can be no doubt that the biochemistry of soil, whether of this world or the next, constitutes one of the most important fields of research of today. This book provides an up to date review of the most outstanding aspects of terrestrial soil, its organisms and living constituents and their interactions. It also gives a brief and tantalizing guide for the assessing of possible organic constituents of the surface material of planets. Under the expert editorship of A. D. McLaren and G. H. Peterson, twenty-three international experts, mostly American, have written specialist chapters. The editors themselves provide an interesting introductory chapter of the biochemistry of terrestrial soils indicating the nature of soil constituents and processes and describing the interactions of living species associative and antagonistic in the soil. The book is divided into three parts: (1) the isolation

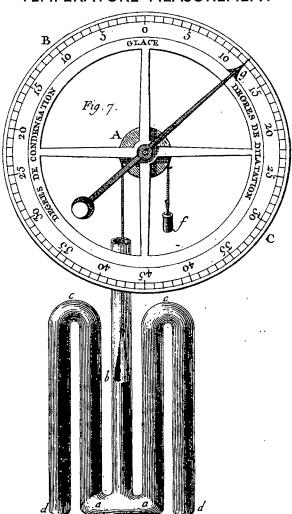

and characterization of soil biochemicals; (2) the metabolism of soil biochemicals; and (3) relationships between soil and microbes. In the first part the organic substances dealt with are general nitrogenous compounds, nucleic acids, carbohydrates, organic acids and free radicals. There is little novelty among the various compounds beyond the fact that they are all clearly constituents of soil. The account of the stable free radicals, such as humic acid in the soil, is timely and interesting. Future studies using electron paramagnetic resonance on the complex soil macro-molecules may throw some light on their complex molecular structure.

The second part covers energy relationships, the biochemistry of the nitrogen cycle, organic sulphates and phosphates, lignin and humic acids and phenolic compounds. Two more important chapters describe the decomposition of herbicides and the degradation of detergents in soils. Concise descriptions are given of various soil enzymes.

The third part discusses the microbiological and biochemical aspects of the rhizosphere, which is the zone of soil in which plant roots exert their influence. All the chapters are written clearly and in great detail, providing a wealth of information with full references. The book will prove of the greatest value to advanced students and to all chemists and biologists.

M. STACEY

TEMPERATURE MEASUREMENT

Berthond's dial thermometer, 1763. From A History of the Thermometer and Its Uses in Meteorology, by W. E. Knowles Middleton. (Johns Hopkins Press; Oxford University Press; 80s.)

(Continued from page 880)

Table 1. CONCENTRATIONS OF NICKEL, GALLIUM, GERMANIUM AND IRIDIUM

Meteorite	Nickel	Gallium	Germanium	Iridium
	(per cent)	(p.p.m.)	(p.p.m.)	(p.p.m.)
Boxhole	7·64	18·1	$\begin{array}{c} 37 \cdot 2 \\ 34 \cdot 2 \\ 37 \cdot 3 \end{array}$	9·1
Henbury	7·44	17·4		15·0
Wolf Creek	9·23	18·4		0·040

Wasson and Goldstein³, so it would have been especially interesting if a relationship were found between two or more of these objects.

Recent work has shown that detailed studies of the chemical composition of iron meteorites can be used to classify these objects into chemical groups, and in addition to define the relationship of the meteorite within a particular group3-5. Studies of the Chilean hexahedrites3 and of the Arizona octahedrites have provided strong evidence that fragments of the same fall tend to be extremely similar in composition. Thus a study of the three Australian irons offered the possibility of testing for compositional indications of a relationship among them.

We have found that most medium octahedrites fall into one or the other of two closely related groups designated IIIA and IIIB. Group IIIA includes irons with 7.4-8.7 per cent nickel, 18-22 p.p.m. gallium, 33-46 p.p.m. germanium, 0.4-17 p.p.m. iridium and structures intermediate between medium and coarse octahedrites. Group IIIB includes objects with 9.2-10.7 per cent nickel, 16-20 p.p.m. gallium, 28-38 p.p.m. germanium, 0.01-0.1 p.p.m. iridium and structures ranging from medium to fine octahedrites. Gallium and germanium are positively correlated with nickel in group IIIA and negatively correlated with nickel in group IIIB. The correlation of iridium with nickel is negative in group IIIA and not yet defined in group IIIB. Nickel has been determined by atomic absorption, and gallium, germanium and iridium by neutron activation.

Table 1 shows the results of duplicate determinations of the four elements in a specimen from Wolf Creek, provided by S. R. Taylor, and in specimens from Boxhole and Henbury, from the Leonard Collection of meteorites at this university. Nickel, gallium and germanium results for the latter two objects are essentially the same as those reported earlier4. Each iron is observed to be unique in composition. There is some overlap in the gallium and germanium contents, but the differences in nickel and iridium concentration are substantially greater than experimental errors. 95 per cent confidence limits are about 1.5 per cent of the reported nickel concentrations, about 10 per cent of the higher iridium values. The Wolf Creek iridium result may be in error by as much as 30 per cent. Boxhole and Henbury are found to be typical low nickel members of group IIIA, whereas Wolf Creek is a typical low nickel member of group IIIB.

This evidence clearly indicates that each of these craters was formed by a unique event. A simple calculation shows that the likelihood of three such events occurring in succession is not unreasonably small. probability of the Earth capturing crater-forming irons of a given structural class is given by the fall statistics cited here for small objects, the probability of three successive cratering events by medium octahedrites is $(0.36)^3$, or a respectable 0.05. The probability is even higher if it is considered that the first event was classestablishing and should be considered separately.

Diffracted S

Gutenberg and Richter¹ commented in 1935 that diffracted S (the S wave diffracted around the Earth's core) was recorded more frequently than diffracted P, but they provided no observational data. To our knowledge, the only reference to observations of S beyond the shadow zone since that time was made by Lehmann², who expressed doubt (on the score of amplitude) whether this or the corresponding P phase were really diffracted waves. Again, no details of arrival times were given. The scant attention paid to diffracted S may be attributed to the fact that it is not listed in the standard travel time tables and consequently is not reported in station bulletins. On the other hand, observations of diffracted P are common, because it appears on seismograms as the first arrival at distances beyond about 100°.

Duwalo and Jacobs3, in a theoretical study of diffraction around a liquid core, have shown that SH waves can be diffracted around the core boundary. At the same time, they pointed out that a diffracted SV wave is not possible, because no shadow zone exists between S and SKS. This provides a criterion for the identification of diffracted S, because core phases such as SKS and SKKS must emerge as SV waves4.

On a number of occasions we have observed, on Canberra records, a phase which satisfies this criterion from earthquakes at distances between 99° and 130°. The phase is detected on long period Press-Ewing horizontal seismometers ($T_s=30$ sec, $T_g=100$ sec) as a single-cycle wave with a period of about 20 sec. It occurs about midway between SKKS and PS, where no other arrival of S type is expected, and can be readily identified in routine analysis of the seismograms.

Table 1 gives details of the earthquakes and the observed travel times, based on information from USCGS PDE cards. The first two events, both from Pakistan, illustrate a method of determining the distance at which S grazes the core-mantle boundary. The particle motion of S from the event at 98.8° distance is unpolarized, while for the other, at 99.6°, it is strongly polarized in the SH direction. This implies that the change from a to unfracted S takes place between these two distances, although further data are needed for verification of the result. No comparable method exists for determining the change from P to diffracted P.

Records of three events included in the table are shown in Fig. 1. The SH nature of the phase can be seen most clearly in the arrivals from Mexico and Panama. Waves from these earthquakes approach Canberra from azimuths which are almost due east. In both cases, the diffracted S arrival appears on the N.-S. seismogram, while the core phases are present on the E.-W. records. Lehmann² likewise noted that two Chilean earthquakes at distances of 106° and 116° and azimuths W.S.W. from Copenhagen gave an S phase visible only on the N.-S. record at Copenhagen. A striking feature of the Panama records is the large amplitude of diffracted S relative to the other phases. We surmise that the fault motion was at right

angles to the direction of Canberra, so that very little P or SV energy was transmitted in this direction.

In Fig. 2, the Jeffreys-Bullen travel time curves are compared with the observed times of diffracted S, SKS1, SKKS, PS and PPS, after corrections for focal depth have been applied. The scatter in the diffracted S readings is similar to that of SKS_1 and SKKS. The readings tend to be about 10 sec later than the predicted times, except for the higher-amplitude PS phase. This may only mean that in most cases the first half-cycle of motion was too weak to be identified with certainty.

The least-squares regression line from the diffracted Sdata has a slope of 8.61 sec/deg, with a standard error of 0.28 sec/deg. The Jeffreys-Bullen S curve has a constant slope of 8.33 sec/deg between 100° and 107°. Records of the events at a number of stations in line with the epicentre could be used to improve the accuracy of the estimate, and to investigate the variation of amplitude with distance, as Sacks has done for diffracted P (refs. 5

Pyroclastic Rocks of the White Mountain Magma Series, New Hampshire

SILICIC volcanic rocks (Moat volcanics) of the White Mountain magma series, which crop out in the Moat Mountain and Mount Kearsarge (Pequawket) areas of northern New Hampshire, USA^{1,2}, are dominantly of pyroclastic origin. The comendites² of these areas are chiefly, if not almost entirely, phenocryst-rich, lithic-poor to moderately lithic-rich tuffs. Most of the tuffs seem to have been densely to moderately welded and probably many, if not most, are of ash-flow origin.

The largest and best exposed body of volcanic material of the White Mountain series is located in the Moat Mountain area immediately north-west of Conway, New Hampshire. Our recent field examination of many of the more accessible outcrops on the Moat Mountain block, supplemented by a thin-section study of geographically and lithologically representative specimens, has revealed that the phenocrysts—chiefly sanidine (now unmixed on a microscopic scale) and quartz—in the comendites are highly fractured. The larger (1 to more than 3 mm) crystal grains commonly show one or more crystal faces, and are unquestionably the fractured remnants of originally euhedral phenocrysts. Of subequal total volume, however, are smaller (1 to less than 0.1 mm) angular crystal grains typically bounded on all sides by generally curved fracture surfaces. There seems little question that nearly all of these smaller grains were originally parts of larger (greater than 3 mm) euhedral phenocrysts. This ubiquitous breakage of intratelluric crystals, usually typical of pyroclastic rocks and presumably resulting from the rapidity and violence of eruption and transport, is probably the strongest single line of evidence for a pyroclastic origin.

Usually indistinct, but unquestionable, eutaxitic (collapsed pumice) structure is visible at a number of localities from the south flank of South Moat Mountain to the north flank of North Moat Mountain and has also been observed in Dry Brook at approximately 1,600 ft. elevation. Numerous boulders showing well preserved eutaxitic structure are also present in the channel of Dry Brook.

The thick (greater than 10,000 ft.) sequence of silicic Moat volcanics in the Moat Mountain area shows pronounced and laterally persistent large-scale layering2. This layering suggests more a sequence composed predominantly of pyroclastic rocks, and particularly of ashflow cooling units, than a thick pile of silicic lavas, which typically form non-stratiform domes, plugs and dikes and relatively irregular and areally restricted flows.

Most of the comendites in the Moat Mountain area contain from 1 per cent to more than 5 per cent of lithic fragments, both of apparently cogenetic volcanic material and of country rock. Although suggesting a pyroclastic origin, the lithic-fragment criterion must here be used with caution because lithic fragments are found in certain apparently non-particulate rocks of the White Mountain magma series.

Although certain eutaxitic structure or large-scale layering has not yet been observed in the comendites exposed on the flanks of Bartlett Mountain in the Mount Kearsarge area, the highly fractured nature of the abundant phenocrystic material in these rocks is strongly suggestive of a pyroclastic origin. The lithic-free to lithicpoor comendites are indistinguishable petrographically from the matrix material of the striking lithic-rich Pequawket breccia, which crops out on the east side of Bartlett Mountain and on Mount Kearsarge. Moreover, there seems to be a continuum of lithologies from lithicpoor comendite to very lithic-rich Pequawket breccia, suggesting that the breccia is largely subaerially deposited pyroclastic material rather than event breccia.

The Moat volcanics are closely associated in space and time with the mineralogically and chemically similar ring dike complexes of the White Mountain magma series¹⁻⁶. The chief bodies of Moat volcanics are partially or completely surrounded by ring dikes and are structurally low with respect to pre-White Mountain basement rocks^{1,2}. The field relations can reasonably be explained either by subsidence of blocks of Moat volcanics along arcuate fault planes now more or less reflected by the ring dikes, by deposition of the Moat volcanics within equant topographic depressions produced by earlier subsidence or by some combination of these two mechanisms. Furthermore, this structural association of at least locally very thick volcanic piles of predominantly pyroclastic origin is consistent with the interpretation (for example, refs. 7-13) of at least some ring dike complexes and cauldron subsidence structures being the lower-level manifestations of main vent areas of the collapse caldera type from which immense volumes of pyroclastic material have been erupted. Such an interpretation is very likely applicable to the White Mountain area. If so, the silicic volcanics, now preserved, are, almost assuredly, only an extremely small fraction of the total volume of pyroclastic material erupted during the activity of the White Mountain province.

PHYSICS

Tracks in Mica caused by Electron

Muons may leave detectable tracks in muscovite mica under suitable conditions such as those found deep underground after the formation of the mica crystals in pegmatites1. The momentum spectrum of the muons, as determined by scattering measurements, indicates the presence of muons of high momentum (>10 GeV/c). It is therefore natural to try to find the products of electromagnetic interactions of the muons, in particular the occurrence of electron showers.

It is well known that high energy electrons show minimum specific ionization and therefore tracks of weaker intensity than those caused by muons are expected. Indeed, there was no prior reason to suppose that electrons could leave detectable tracks in mica. Because ionization occurs principally by delta ray formation, however, it is not unreasonable to assume that at localized regions along the track of an electron the specific ionization could be sufficiently above average to produce a nucleation centre. These infrequent centres would then be decorated by the exolving iron during the sensitive phase of the mica crystal. The resulting track would take the form of a random sequence of decorated nucleation centres showing no obvious correlation other than being approximately rectilinear. For the track of an electron to be detectable. however, there must be a sufficient number of such decorated centres within a radiation length of mica to be noticeable above the background. For high energy muons the distance between nucleation centres is of the order of microns while the radiation length in mica is about 10 cm or 105μ, which suggests that there is considerable latitude in the possible mean spacing of nucleation centres which would result in a recognizable track.

An additional factor in the possible detection of electron tracks is the relatively large extent of multiple scattering. which, together with the known restriction in angle perpendicular to the (001) plane for the recording of tracks, suggests that the track of an electron would be split up into a series of short sections. Whenever the track lies within the detection range in angle and the specific ionization is sufficiently high, then a section of track might be recorded. The combination of these two factors suggests that the spacing between decorated centres might well be several orders of magnitude greater than for muon tracks, possibly about 1 mm or 103 µ.

The existence of a restriction on the angle of a track for it to be recorded out of the (001) plane should not be a limitation in the detection of an electron shower because of the relatively large range of angles of tracks of electrons in a shower as a result of both the opening angle in pair formation and the effect of multiple scattering. Indeed, it might be fortuitous in preventing overcrowding of tracks. In consequence, tracks caused by an electron shower should exhibit a definite correlation in direction throughout an appreciable thickness of mica in a direction perpendicular to both the (001) plane and the axis of the shower. Such behaviour would be in sharp contrast to that of the tracks of muons from neutrino interactions deep underground.

A search was made for evidence of electron showers in a quantity of muscovite mica which showed tracks of muons. The mica, of commercial S.D.B. type, came from both India and Africa. Definite evidence for the occurrence of electron showers was found and is summarized here.

Many rectilinear sequences of decoration centres were found which showed a spread in angle in the (001) plane of a few degrees, were confined closely to the (001) plane and showed correlation of direction. Such arrays were also observed to show correlation of direction throughout appreciable thickness, t, of the blocks examined, as indicated in Fig. 1. Observations were restricted to specimens showing no structural damage and little internal decoration.

In Fig. 2, the length distribution of tracks in several blocks of mica, which extended over a thickness totalling more than 1 cm of crystal, is shown. The median of the distribution is about 6.3 cm. Because the root mean square value of the atomic number for muscovite is about 10.0, the radiation length is roughly 10.6 cm, which implies that the most probable length of track before a radiative collision occurs is about 7.8 cm. Multiple scattering will tend to shorten the observable length of a track and so the observed median is in good agreement with the predicted length.

Measurements have been made on the spacing between decoration centres and yield a median value of 2,200μ. It is instructive to plot the results in order to show how the number of gaps of length equal to or greater than a given length vary with the length, for it has been shown² that in emulsions there is an exponential relationship for a given specific ionization. Because the phenomenon under

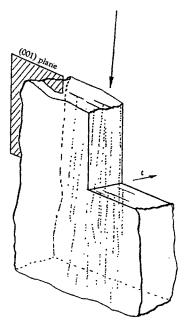

Fig. 1. Diagram showing the penetration of an electron shower into a crystal over a considerable thickness t.

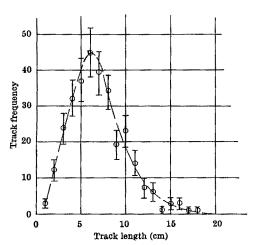

Fig. 2. Length distribution of the electron tracks.

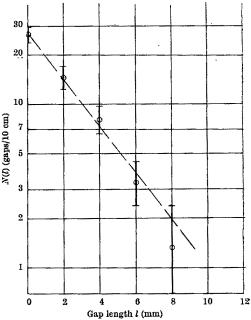

Fig. 3. A plot of the number of gaps of length $\geqslant l$ as a function of l.

Fig. 4. Photograph of part of the tracks of an electron shower in muscovite mica.

lying detection of particles in both emulsions and mica is believed to be similar, in that it is mediated by delta rays, it is reasonable to expect a similar behaviour. The results are shown in Fig. 3 and clearly support this hypothesis.

In Fig. 4 a photograph of part of a shower is shown. It is evident that the coarseness of the decoration prevents measurements of the energy of an electron from the multiple scattering of its track, but this might be estimated from the longitudinal or lateral extent of the observed shower³.

Because mica crystals are comparable in size with the lateral extent of showers the dominant factor in the detection efficiency is the angular spread of tracks within a shower as opposed to the high angular selectivity imposed for individual tracks. This enhanced efficiency of detection for showers could be useful in permitting a relative study of the high energy region of the muon spectrum, as the probability of an electromagnetic interaction of a muon as a function of energy is known⁴. A preliminary study indicates that the average probability for shower production is less than I per cent per muon, indicating a relatively low mean energy for the muons ($\ll 100 \text{ GeV}$).

(≪100 GeV).

With regard to the origin of the observed electron showers, it is relevant that the tracks of muons occurring in the same mica showed no definite evidence of a cos⁰0-type dependence on relative orientation, suggesting a predominantly neutrino induced muon origin. The implied

low mean energy of the muons is also consistent with a neutrino-muon origin for the showers.

Order-Disorder Transformation in Potassium Graphite

During an X-ray diffraction investigation of the potassium graphites¹, we concluded that the reduction in potassium concentration within the intercalate layer, which occurs on passing from stage 1 (C_8K) to stage n ($C_{12n}K$), is accompanied by a loss of long range order within the layer. A study of the stage 2 compound has now shown that this disordered intercalate structure (form I) transforms reversibly to an ordered state (form II) at a temperature of about -175° C.

The specimen was prepared from annealed, hot-pressed pyrolytic graphite² by the two bulb method of Herold³. The second bulb, which contained the graphite, was in the form of a thin walled capillary tube; after the compound had been formed, this capillary tube was sealed off and transferred to the X-ray goniometer. The change in diffraction pattern on transformation from form I to II is shown diagrammatically in Fig. 1. Scattering from the intercalated potassium gives rise to a single streak (S) in form I, but in form II there are khl superlattice reflexions on at least six row lines (S1 to S6). Thus the development of order within the intercalate at the transformation temperature is not restricted to individual layers but extends to three dimensions.

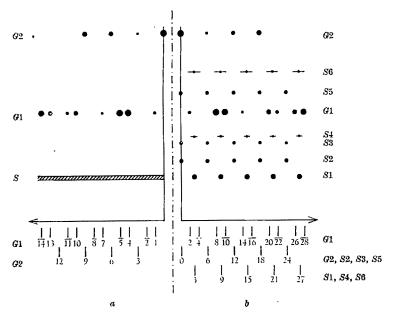

Fig. 1. Schematic representation of the change in the X-ray diffraction pattern during the order-disorder transformation in potassium graphite (stage 2). a, Form I, room temperature; b, form II, liquid nitrogen temperature. Each diagram is equivalent to a rotation photograph about the horizontal c-axis and numerical values of l to be associated with each layer line are indicated. Row lines of constant h and k are denoted by G if carbon atoms contribute to the reflexion and by S if the diffraction effect is due solely to potassium atoms.

A significant finding is that no detectable change in relative intensity or resolution of reflexions which index in form I as $10\overline{1}l$ and $11\overline{2}l$ (G1 and G2) occurs at the transformation temperature. From this it follows that two conclusions regarding the structure of form I are also valid for form II. These are¹: (a) the potassium atoms are located over the centres of hexagons of carbon atoms; (b) the graphite layer stacking sequence is AB|BC|CA|A. The first condition implies that displacements of the potassium atoms within any intercalate layer during the transformation to the ordered state must be expressible in terms of unit displacements which are of the type

 $\frac{a}{2}$ < 11 $\overline{2}$ 0 > (numerically equal to the translational repeat

distance, a, of the two-dimensional graphite lattice). Taken together, these two conditions impose a restriction on the intercalate layer stacking vector, t. The two-dimensional intercalate lattice must follow the graphite layer stacking sequence if potassium atoms are to remain over the centres of carbon hexagons. The vector t must there-

fore include a vector of the type $g = \frac{a}{3} < 10\text{T0}>$ which

changes the graphite layer orientation in the sequence $A \rightarrow B \rightarrow C \rightarrow A$.

In the simplest case, the periodicity of the stacking sequence of the graphite and intercalate sub-lattices would be identical and the intercalate stacking sequence could then be represented by $\alpha \beta \gamma \alpha \dots$ This would not account, however, for the position of reflexions on row lines S1, S4 and S6 which imply that the c-axis repeat distance doubles during the transformation from form I to II. The intercalate stacking sequence must therefore be of the type $\alpha \beta \gamma \delta \epsilon \eta \alpha \dots A$ simple relation between $\alpha \beta \gamma$ and δεη is suggested by the fact that there are extensive systematic absences within the superlattice row lines; hkl reflexions are present only when l = 6n in S2, S3 and S5 and when l = 6n + 3 in S1, S4 and S6. The sequence $\delta \varepsilon \eta$ is probably a displacement of the sequence $\alpha \beta \gamma$, parallel to the graphite planes and of a magnitude sufficient to introduce a phase shift of about 0 or π according to the numerical values of h and k to be associ-

ated with a particular row line. It is therefore proposed that the combined intercalate-layer and graphite-layer stacking sequence can be schematically represented by A α^1 A B β_1 B C γ_1 C A α_2 A B β_2 B C γ_2 C A α_1 A . . . where $\alpha,\ \beta$ and γ differ at least by successive displacements of g and where the change of subscript denotes a translation which approximately centres the intercalate lattice. This stacking sequence repeats after about 52 Å.

The displacement which changes at into α₂ can only arise through a direct interaction between these two layers, because the carbon atom environments of α_1 and α_2 are identical. Evidence for intercalate layer interaction over similar distances was also found in the order-disorder transformation of the graphite nitrates4. In these compounds also, the stacking repeat distance doubles during the transformation I->II, but the detailed interpretation of the diffraction patterns given by stages 2, 3 and 4 was complicated by the presence of some unmodulated row lines which were assumed to be caused by extensive intercalate stacking disorder. The simpler diffraction pattern for potassium graphite presumably reflects the difference in structural complexity between intercalate layers which contain atomic and molecular species, respectively. theless, the definition of reflexions in the row

lines which distinguish α_1 from α_2 falls off in the sequence S1, S4 and S6. A likely explanation is that even here there is some random element of structure, either within a single intercalate layer or in the intercalate layer stacking sequence.

THE SOLID STATE

Cleavage of Zinc Single Crystals induced by Stress Waves

WE report some observations of the dynamic cleavage of specially oriented single crystals of zinc by the reflected stress wave technique. Kolsky¹ has used this technique for studying the brittle fracture of glass and polymeric solids.

Zinc crystals² with a diameter of about 8 mm, a length of about 60 mm and with their potential cleavage plane (0001) perpendicular to the rod axis, were loaded with the stress wave produced by hitting a transmitter bar with a flat-faced projectile, as shown in Fig. 1. Fractures were produced by the tensile wave reflected from the interface between the zinc and styrofoam. This procedure eliminates the problems involved in gripping the specimen and reduces the problem of specimen alignment. For this crystal orientation, the shear stress on the primary slip plane (0001) < 1120> is nominally zero. Earlier static tests3-6 on zinc crystals have indicated that the stress

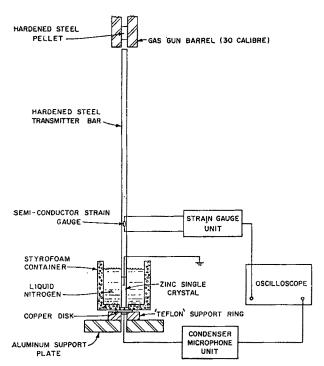

Fig. 1. Schematic diagram of testing arrangement,

required for twinning or for slip on secondary slip systems is comparable with the cleavage fracture stress.

The peak value of the stress wave transmitted to the zinc single crystal can be computed as the difference between the peak values of the incident and reflected waves in the transmitter bar. Cleavage was consistently observed for transmitted stress pulses with an amplitude greater than 16×10^8 dynes/cm² and a duration of $10~\mu sec$. Determination of the actual stress at fracture is difficult because the pulse is attenuated as it propagates in the zinc crystal as a result of plastic deformation and because it is not clear whether fracture has occurred at the peak value of the pulse or at some lower value. An attempt to allow for these factors was made by using a condenser microphone, to obtain a record of the displacement of the zinc-styrofoam interface. Further work will be necessary before reliable values of the fracture stress can be given.

The cleavage surfaces were examined optically and with various X-ray diffraction techniques. The dynamically fractured surfaces seemed to be optically more specular than any which could be produced by cleaving crystals with a razor blade at liquid nitrogen temperature. The general indication from Laue back-reflexion photographs, Schultz pictures and Berg-Barrett X-ray diffraction contrast micrographs is that the dynamically fractured crystals exhibit cleavage surfaces which are appreciably less deformed than the surfaces of crystals cleaved with An unfractured crystal which was repeatedly loaded became so deformed, however, that the Bragg condition was no longer obeyed over local areas greater than about 100µ in diameter.

The conclusion is that the technique is useful for studying cleavage fracture, at least in zinc crystals, in conditions for which the pre-fracture plastic flow is minimized.

This work was supported by the Army Research Office (Durham), the US National Science Foundation and the Advanced Research Projects Agency of the Department of Defense.

MOLECULAR STRUCTURE

Role of Van der Waals Interaction on Hindered Rotation about Single **Bonds in Simple Molecules**

The hindrance of rotation about single bonds has recently attracted considerable interest $^{1-3}$ because it greatly influences the physical and chemical properties of many organic molecules. The importance of rotations about single bonds in synthetic and biological macromolecules has also been emphasized and successful attempts have been made to derive the most stable conformations of linear macromolecules considering this effect⁴⁻¹⁰.

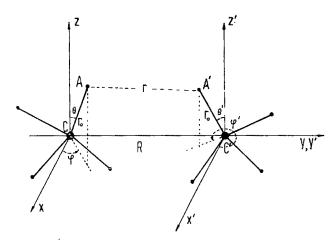

Fig. 1. Geometrical representation of two methane molecules in interaction $(r_0; CH=1.09 \text{ Å}, CF=1.32 \text{ Å}, CCl=1.77 \text{ Å}).$

In attempting to explain the presence of potential barriers which hinder rotations about single bonds, in molecules like ethane and ethane derivatives, there have been two principal approaches. According to several authors, the barriers arise from the lack of cylindrical symmetry in the molecular orbitals describing the obonds¹¹. Another approach emphasizes the importance of steric hindrance resulting from Van der Waals interactions between the non-bonded atoms which depend on rotation about the bonds¹².

Scott and Scheraga³ have tried to reconcile both views. While investigating the conformational analysis of macromolecules we have independently adopted a similar approach and have carried out systematic calculations on a number of molecules which we report here.

In order to evaluate the relative importance of Van der Waals interactions and torsional potential, we considered it useful to submit the various functions so far proposed to describe pairwise interactions between non-bonded atoms to an indirect experimental test. In particular, the carbon-carbon, hydrogen-hydrogen, fluorine fluorine, chlorine-chlorine and the mixed interactions were considered.

A reasonable criterion for such a test seemed to be the calculation of the intermolecular potential as a function of the distance between a pair of methane, carbon tetrafluoride or carbon tetrachloride molecules which has been derived from experimental data with a certain degree of accuracy¹³.

When the interactions between two methane molecules are calculated, it is necessary to consider the effect of the distance between the carbon atoms as well as the reciprocal orientation of the two molecules. Because the intermolecular potential was derived assuming spherical symmetry the following equation was used

$$V(R) = \frac{1}{4\pi^2} \int d\omega \mid d\omega' v(r)$$
 (1)

where $d\omega = \sin\theta \; d\theta \; d\phi; \; d\omega' = \sin\theta' \; d\theta' \; d\phi' \; {\rm and}$

$$v(r) = \Sigma_{j} \left(\frac{a_{j} \exp \left(-b_{j} r_{j}\right)}{r_{j} d_{j}} - \frac{c_{j}}{r_{j}^{6}} \right)$$

The summation on j is extended to all pairs of atoms in the two molecules.

The same equation was used to calculate the intermolecular potential between two carbon tetrafluoride and carbon tetrachloride molecules. The variables θ , φ , θ' , φ' , r and R are defined in Fig. 1. The parameters a_1 , b_1 , c_2 and d_3 of the various functions tested are listed in Tables 1, 2 and 3. It must be pointed out that when $d_1 = 0$, the function is of the Buckingham type, and if $b_1 = 0$ and $d_1 = 12$, it is of the Lennard-Jones type. Some authors used one type to describe the carbon-carbon interaction and the other for the hydrogen-hydrogen interaction. This means that the mixed carbon-hydrogen potential

Table 1. POTENTIAL FUNCTIONS BETWEEN CARBON AND HYDROGEN ATOMS

Parameters a and c are given, respectively, in kcal AdMole⁻¹ and kcal AdMole⁻¹ unit.

(a) As this author did not propose a function for the carbon—carbon interaction, we have used the one proposed by Bartell¹⁸ fitted by a Buckingham type function. The same one has been adopted for the carbon—carbon interaction of set 7.

(b) This set of parameters has been derived from the Bartell's function in a way fully described in the text.

Table 2. POTENTIAL FUNCTIONS BETWEEN CARBON AND FLUORINE ATOMS

No. of		Carbon-carbon					Fluorine-fluorine				Carbon-fluorine			
set	Ref.	$a \times 10^{-3}$	b	c	d	$a \times 10^{-3}$	b	\boldsymbol{c}	d	$a \times 10^{-3}$	b	c	d	
1	3	528-0	4.58	370.0	0.0	60-2	4.60	118.0	0.0	152.0	4.59	200.0	0.0

(b)						106-0	4.61	125.0	0.0					

The mixed interaction carbon-fluorine of set 2 was calculated with the same method as that described in the text for the carbon-hydrogen one. It is therefore slightly different from the corresponding one in ref. 6. Set 2a is valid for r < 2.9 Å and set 2b for r > 2.9 Å.

Table 3. POTENTIAL FUNCTIONS BETWEEN CARBON AND CHLORINE ATOMS

No. of		Carbon-carbon			Chlorine-chlorine				Carbon-chlorine				
set	Ref.	$a \times 10^{-8}$	b	c	d	$a \times 10^{-3}$	b	c	d	$a \times 10^{-3}$	b	c	ď
1 2 3 (a) (b)	14 3 5	237·0 528·0 237·0	4·32 4·58 4·32	298-0 370-0 298-0	0·0 0·0	260·0 314·0 13·0 221·0	3·67 3·75 0·0 3·62	1,811.0 2,520.0 0.0 1,430.0	0·0 0·0 7·87 0·0	248·0 425·0 239·0	4·17 3·97	732·0 975·0 653·0	0.0 0.0

The same remark as that given in Table 2 for the carbon–fluorine interaction is also valid for the earbon–chlorine interaction of set 3. Set 3a is valid for r < 3.0 Å and set 3b for r > 3.0 Å.

shows an r dependence characterized by a value of $b_i \neq 0$ and $d_i = 6$. To allow a direct comparison of the coefficients used by different authors, those corresponding to the same types of function are clustered in Table 1.

The intermolecular potential was calculated according to equation (1), with the aid of an IBM 7040 computer, and angular increments $\Delta \varphi$, $\Delta \theta$, $\Delta \varphi'$ and $\Delta \theta'$ of 30° were considered. It was observed that smaller increments would not increase the accuracy by more than a few per

The results for methane are shown in Fig. 2a and b. The intermolecular potentials calculated with most of the functions recently proposed are shown in Fig. 2b. From Fig. 2a and b, curves 7 and 8 are seen to give the best agreement with experimental results. Curve 7 differs from curve 8 in the choice of a Buckingham type function to describe the carbon-carbon interaction instead of a Lennard-Jones one and in the means used to derive the mixed interaction.

The parameters of the mixed interaction of curve 7 were, in fact, obtained by finding the geometrical mean of the attractive term and of the part of the repulsive term which depends on r. The remaining parameter a was obtained by imposing the condition that the function must be minimum at the sum of the Van der Waals distance given in Table 4. In curve 8, proposed by Bartell, the geometrical mean was calculated from the repulsive term, and the parameter c was then calculated from the same minimum requirement.

le 4. Potential functions used to calculate van der waals con-tribution to the rotation barrier of ethane-like molecules

V(r) =		<u>c</u> .s a	ь	c	d	<i>r</i> min
H-H		6.60	4.08	49.2	0.0	2.96
F-F	r < 2·3 r > 2·3	7·2 106·0	0·0 4·61	0·0 125·0	0·0 9·99	3.14
·ClCl	r < 3.0 r > 3.0	13·0 221·0	0·0 3·62	0·0 1.430·0	7·87 0·0	3.86
H-F		21.4	4.34	78-5	0.0	2.97
H-Cl		33.8	3.85	265.0	0.0	3.33
FCI		172.0	4.11	423.0	0.0	3.50

To calculate the coefficients of the mixed interactions hydrogen-fluorine and hydrogen-chlorine, a Van der Waals radius of 1.4 Å was taken for the hydrogen atom instead of 1.48 Å in the hydrogen-hydrogen interaction.

Table 5. COMPARISON BETWEEN OBSERVED AND CALCULATED POTENTIAL BARRIERS

	DAIMANAG											
Molecules	Van der Waals energy barrier	Total energy barrier	Experimental values									
1 CH ₃ -CH ₂ 2 CF ₃ -CF ₃ 3 COl ₃ -CCl ₃ 4 CH ₃ -CCl ₃ 5 CH ₃ -CCl ₃ 6 CF ₃ -CCl ₃ 7 CH ₃ -CH ₄ F 8 CH ₃ -CH ₄ F 9 CH ₃ -CH ₅ Cl 10 CH ₃ -CH ₅ Cl	0·42 1·95 9·34 0·69 1·71 5·69 0·51 0·60 0·84 1·27	3·12 4·65 12·04 3·39 4·41 8·89 3·21 3·30 3·54 3·97	3·0 4·0 12·0 3·7 3·0 13·0 8·3 3·4 4·0									
10 CH ₃ -CHCl ₂	1.21	5.81	9.0									

All angles are assumed to be tetrahedral. The bond distances used are

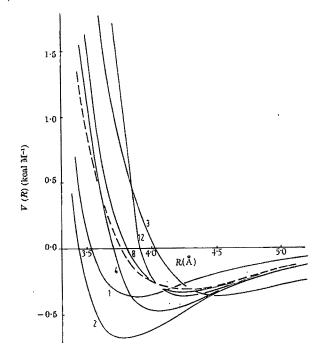

Carbon-carbon = 1.54 Å
Carbon-hydrogen = 1-09 Å
Carbon-fluorine = 1.33 Å
Carbon-fluorine = 1.76 Å

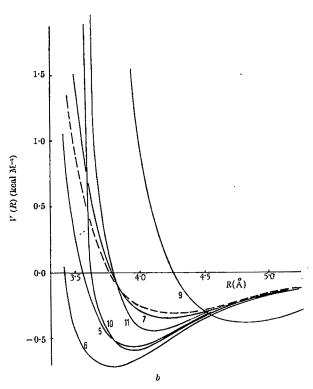

The energy values are given in kcal/Mole. The total energy barrier is the sum of the Van der Waals contribution and a unique torsional potential taken equal to 2.7 kcal/Mole.

Tables 2 and 3 give the data of an identical calculation carried out for the carbon tetrafluoride and carbon tetrachloride molecules.

From experimental curves shown in Figs. 3 and 4, it appears that curves 2 and 3, respectively, derived from Bartell's carbon-carbon interaction and the rare gas approximation introduced by Mason and Krevoy12, are the best. It should be pointed out that these functions were used in our laboratory a few years ago5 to derive quite successfully the most stable conformation of a lot of synthetic polymers.

Fig. 3 also shows the results of an electrostatic test. This test was carried out on the assumption that small charges approximately equal to one third of those producing the experimental dipole of a carbon-fluorine bond

. a and b, Calculated potential energy between two methane molecules. The dotted line represents experimental data.

are localized on the fluorine and carbon atoms. At first sight it seems that this procedure gives the best agreement within the whole range of R values. Nevertheless, it must be remembered that, in such a case, polarization contributions also occur. These terms are attractive and so could very well balance the repulsive electrostatic ones at intermediate distances.

In order to calculate the barriers to internal rotation in ethane and halogene substituted ethanes, the following equation has been used to obtain the potential energy as

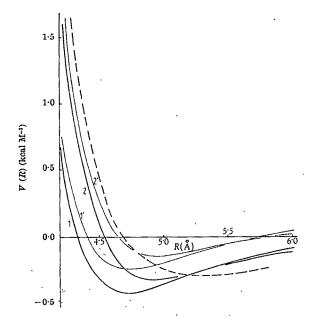

Fig. 3. Calculated potential energy between two carbon tetrafluoride molecules. Carves 1' and 2' were calculated with the same Van der Waals function as curves 1 and 2, but also taking into account an electrostatic contribution arising from a charge equal to $-0.07 \times e$ localized on each fluorine atom and $0.28 \times e$ on the carbon atoms.

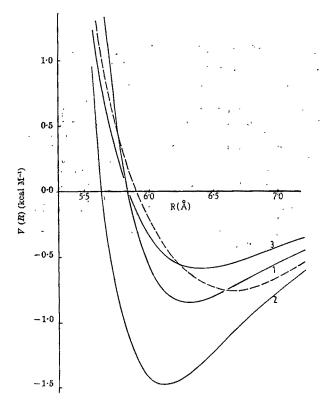

Fig. 4. Calculated potential energy between two carbon tetrachloride molecules.

a function of the angle of rotation about the carbon-carbon

$$E(\psi) = \Sigma_j a_j \exp(-b_j r) - c_j 2^{-8} + \frac{V_0}{2} (1 + \cos 3\psi)$$
 (2)

When the parameters of curve 7 described in Table 2 were used to calculate the Van der Waals contribution corresponding to the first term of equation (2) and a value of $V_0 = 2.7$ kcal was used for the torsional potential

barrier, the results listed in Table 4 were obtained. The agreement between experimental^{2,3} and calculated potential barriers seems rather good in view of the simplicity of the approach used.

CHEMISTRY

Reactivity of Trapped Free Radicals in Biological Systems

IRRADIATED poly-crystalline amino-acids lend themselves to the kinetic investigation of radical stabilities, because radicals can be induced readily in solid amino-acid by irradiation and because radical concentrations at different temperatures can be followed conveniently by electron spin resonance spectroscopy. In this study, radicals were formed in a number of amino-acids containing sulphur by irradiation at 2537 Å with a low-pressure mercury-vapour germicidal lamp¹. Electron spin resonance spectra were determined on a JEOL-3BX electron spin resonance spectrometer. Samples were usually irradiated continuously at room temperature until the concentration of radicals remained constant and decay rates were then studied at higher temperatures; it was assumed that the radical concentration present was proportional to the signal strength, which was estimated directly from the recorded spectral trace using a planimeter.

L-Homocysteine, L-cysteine hydrochloride and L-penicillamine, but not L-cystine, all gave decay curves which, in the absence of air, fitted a single second order function for the majority of the decay times. A typical curve is shown in Fig. 1. Because irradiation with 2537 Å light is known to form radicals preferentially near the crystal surface*.

* This was also confirmed by irradiating a single crystal of L-cysteine hydrochloride, when appreciable radical concentrations could only be detected in the irradiated portions. We are indebted to Professor J. R. Bolton for suggesting this experiment.

one would anticipate the observed decay curve to be the composite of a series of second order curves, one for each of the RS radical pairs present depending on their distance from each other. That is, radicals nearer the surface, being closer to each other, would be anticipated to combine more readily than more isolated radicals formed further away from the crystal surface. Because most of the observed points lie on a single second-order decay curve, it is assumed that an initial, faster, randomizing, reaction occurs. A probable, more specific, explanation is that a reaction of type (1) occurs first, which is followed by a second, slower, rate-determining step (2).

RS· (formed during irradiation) + RSH
$$\rightarrow$$
 RSH + RS·* (1

$$RS^{*} + RS^{*} \rightarrow Products$$
 (2)

In these equations, RS.* represents the eventually trapped species, the recombination rate of which is measured in the experiments. RS. may itself represent the formation of a secondary radical (compare with ref. 2) and radicals such as H· and R· are presumably also formed. The electron spin resonance spectra at 77° K and room temperature, however, indicate predominantly the presence of RS. species only. That is, signal shape and g values show the electron to be located predominantly on the sulphur atom and no significant change in signal shape was detected during the build-up or decay of the radical concentrations. No appreciable line-broadening was detected between 77° K and room temperature.

The simplest way to explain the presence of randomly distributed radicals is to assume that, given favourable steric conditions, hydrogen transfer occurs between neighbouring SH groups (step 1) until the unpaired electron is located on a sulphur atom (RS·*), which is no longer near to another hydrogen atom and no further reactions of type (1) then occur. The actual mechanism of step (1) is uncertain, but may involve an intermediate of type RSHSR (compare with ref. 3, where a similar species has been postulated to account for the low energy required for the transfer of hydrogen atoms in solution). The occurrence of step (1), incidentally, can account for the relatively small saturation concentration of radicals, formed on irradiation⁴, and for the previously noted phenomenon of radical site migration in irradiated solids⁵.

Of considerable interest are the observed energies of activation for step (2), which were found to lie between about 9-25 kcal/mole. Because step (1) must possess a smaller energy of activation, the data suggest that effective free radical site migration can occur in these solids with a relatively low energy of activation (compare also with ref. 6 where, for migration processes within proteins, activation energies of 70 cal/mole and 2·2 cal/mole have

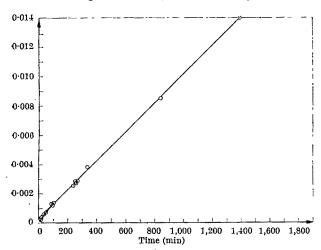

Fig. 1. Decay diagram for 2537 Å-irradiated polycrystalline L-penicillamine in vacuum at 120° C, plotting time versus $(\{R^-\}_b - \{R^-\}_o)/(\{R^-\}_b - \{R^-\}_\omega)$, where $\{R^-\}_b$, $\{R^-\}_t$ and $\{R^+\}_\omega$ are the relative radical concentrations at time 0, t and ω , respectively.

been reported). This finding, it substantiated by further experiments, indicates a mechanism of how free radicals, once formed—for example, through inhaling of tobacco smoke or soot—may migrate through biological materials to reach sensitive sites.

Origin of Linewidth Alternation in Semiquinone-Alkali Metal Systems

The electron spin resonance spectra of semiquinone-alkali metal systems in 1,2-dimethoxyethane (DME) have recently been interpreted in terms of (a) two types of ionpair, A or solvated type and B or contact type, which appear separately or together depending on the temperature and (b) an equilibrium between these two types of ion-pair which is thought to be the cause of marked linewidth alternation. We have also studied these systems over a wide temperature range, but have drawn quite different conclusions.

We will consider only those spectra which show hyperfine coupling from diamagnetic gegenions because if this is detected there can be no doubt of the presence of ion-pairs². In particular the sodium salt of durosemiquinone in

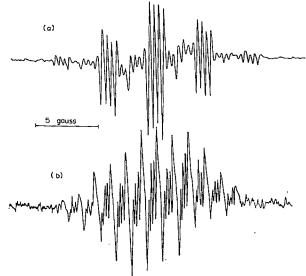

Fig. 1. Electron spin resonance spectra of the sodium salt of duro-semiquinone in DME at $(a) + 20^{\circ}$, $(b) - 90^{\circ}$.

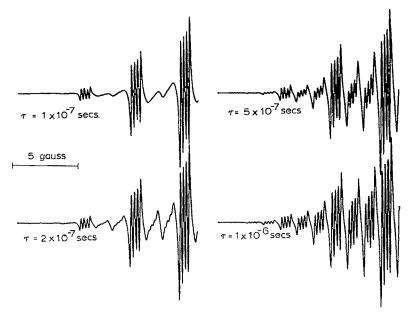

Fig. 2. Computer simulations, for various τ (ref. 7), of the electron spin resonance spectrum of the sodium salt of durosemiquinone assuming an intramolecular migration between equivalent sites.

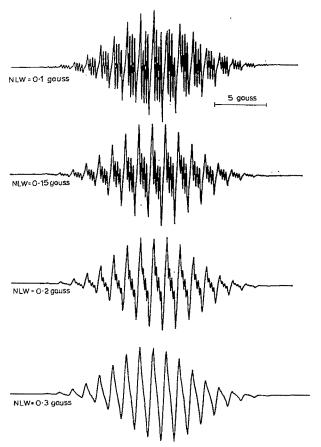

Fig. 3. Computer simulations, for different natural linewidths (NLW), of the electron spin resonance spectrum of the sodium salt of duro-semiquinone assuming no intramolecular migration, that is, large τ (ref. 7).

t-pentanol, DME and tetrahydrofuran (THF) will illustrate our case.

If an equilibrium exists between two types of ion-pair in which the same sodium ion is involved so that its nuclear spin state is retained, either one or two sets of

hyperfine lines will be detected depending on the rate of equilibration. If this is rapid, the outer pair of lines will usually be broader than the inner pair2 because the hyperfine lines arising from the spin states, $m_s = \pm 3/2$, span a larger range of field than the $m_s = \pm 1/2$ lines. This should be particularly apparent from the quartet at the centre of the durosemiquinone spectrum, where, in the absence of a large g-shift between the different ion-pairs. the central anion hyperfine component is unaffected by the exchange. No variation in the linewidths of the central quartet has been observed for the sodium salt of durosemiquinone in DME, as shown in Fig. 1 (see also Fig. 2 in ref. 1) or in t-pentanol3, although in the overall spectra alternating linewidth effects, indicative of an exchange, are dominant. This shows that an equilibrium between two structurally different ion-pairs, which have very different sodium hyperfine coupling constants, is not responsible for the observed We conclude that the more spectra. common concept2 of intramolecular migration of the cation between two equivalent sites on the anion is the only one so far suggested which will agree with all the

observations. In the absence of hyperfine coupling from diamagnetic gegenions the conclusions are ambiguous, but there seems to be no reason to assign a different mechanism.

Although different types of ion-pair have been detected by electron spin resonance6, the only clear cut example of this with semiquinones has been with 2,6-dimethyl-pbenzosemiquinone^{4,5}, the difference being one of site rather than solvation. The symmetrically substituted semiquinones, for example, durosemiquinone, are unable to behave in this way and so we have examined our spectra for any evidence that two types of ion-pair1 do occur in these systems. Our spectra (Fig. 1) seem to be very similar to those previously published1, over a range of temperature. We have, however, been able to analyse each spectrum in terms of one radical with hyperfine coupling constants: $a_1^{\text{Me}} = 1.25$; $a_2^{\text{Me}} = 2.55$; $a^{\text{Na}} = 0.23$ gauss at -90° C or $a_1^{\text{Me}} + a_2^{\text{Me}} = 3.8$; $a^{\text{Na}} = 0.37$ gauss at 20° ('. Using the coupling constants at -90° we have calculated theoretical spectra with a natural linewidth of 0-1 gauss and for various rates of intramolecular migration expressed as a function of the lifetimes, τ , in Fig. 2. The effect of different natural linewidths on the spectrum for slow rates of migration, that is, at low temperatures, is quite significant and is shown in Fig. 3. Comparison of these calculated spectra with the experimental (see also Fig. 2 of ref. 1) shows that the experimental spectra are well interpreted with one species with an intramolecular migration of the cation between equivalent sites. It seems that the spectrum assigned to two different species1 is purely an unfortunate artefact of overlapping lines.

PHYSIOLOGY

Antidiuretic Activity in the Pituitary Gland of the Koala Bear

Arginine or lysine vasopressin is found in the pituitaries of most placental mammals and arginine vasopressin has been tentatively identified in a monotreme¹ and in four species of marsupials1,2. We have investigated antidiuretic activity in the pituitary of a young koala bear (Phascolarctos cinereus), which is of interest because this animal is rarely, if ever, known to drink, its water intake being derived solely from eucalyptus leaves.

The koala studied was about 6 months old and thus quite immature, and had died by falling out of its mother's pouch during the night. The pituitary gland was extracted according to standard methods³ and assayed against 'Pitressin' (Parke, Davis and Co.) in the hydrated rat⁴ with an initial and maintained water load equivalent to 6 per cent of its body weight. We have found this slightly lower level of hydration to produce a satisfactory flow of urine and to improve the sensitivity to injected vasopressin. Sections of hypothalamus and medulla were similarly extracted and assayed for antidiuretic activity.

The antidiuretic activity of the whole pituitary was equivalent to 235 mu or 7.95 mu/mg dry tissue which, considering the age of the koala, seems comparable with that reported for other marsupials. It is tentatively ascribed to vasopressin because the log dose-response curves of the standard and extract were parallel, the standard and extract produced similar effects on urine volume and conductivity both in onset and duration and the activity was destroyed by incubation with 0:01 molar sodium thioglycollate for 30 min (ref. 4). There was no detectable antidiuretic activity in the extracts of hypothalamus and medulla, the lower limit of sensitivity in the assay animal being $1.25 \mu U$.

The koala was collected by Dr P. A. Robertson of Lone Pine Sanctuary, Brisbane. We thank the Australian Wool Board for financial assistance.

Siphuncular Tube of Nautilus

SINCE Robert Hooke¹ suggested that the siphuncle (which he took to be the gut) of Nautilus produced gas to force liquid from the shell chambers and so buoy up the animal, there have been many speculations on its function. These speculations required that the siphuncular tube was watertight², or air-tight³⁻⁵, or permeable to gas⁶⁻⁸, or permeable to liquid^{9,10} or permeable to both gas and liquid¹¹. The only experimental information, however, on the transmission properties of the siphuncular tube is that it is permeable to water¹⁰. The experiments described here show that the wall of the siphuncular tube is permeable to sea water (with a linear relationship between flow rate and pressure), impermeable to air and able to withstand pressures equivalent to well above 450 m of water.

A fresh shell of Nautilus macromphalus was sawn open along the dorsoventral plane. Stainless steel tubes were bonded with 'Araldite' to the siphuncular tube openings

so that sea water could enter into the first chamber adjacent to the living chamber, and could leave from the fifth chamber. The inflow tube was connected to the pressure apparatus (Fig. 1) and the outflow tube to a bleed valve. Initially, sea water was forced in under a head of 41 m of water, and immediately small beads of liquid appeared on the surface of the siphuncular tube. In each segment, the beads coalesced into a single drop of liquid at intervals of about 5 min. When the pressure was increased, the flow rate of liquid was found to be directly proportional to the pressure (Fig. 2). At a 205 m head, the five chambers were almost half full of transmitted liquid after an hour.

In a further experiment, sea water under 205 m head was forced into the siphuncular tube segments in the earliest twenty shell chambers. Liquid appeared on the siphuncular tube segments in all chambers except the earliest one. With this exception, all the siphuncular tube segments seem to be functional, even the earliest seven segments which supposedly formed in the egg. Thus at 200 m depth a Nautilus shell would fill in about 2 h if the siphuncle did not prevent it.

The salinity of the effluent at various pressure heads up to 200 m was analysed and found to be unaltered from that of the inflowing sea water, so that the siphuncular tube seems to act as a permeable, not a semi-permeable. membrane. A reduction in salinity would have explained

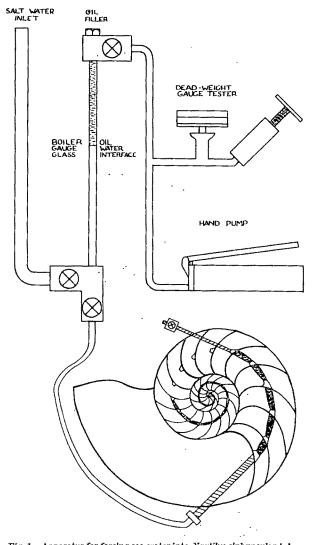

Fig. 1. Apparatus for forcing sea water into *Nautilus* siphuncular tube. Permeable parts of siphuncular tube in black.

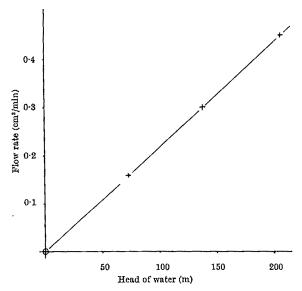

Fig. 2. Flow through the walls of the siphuncular tube.

the low salinity values that Denton and Gilpin-Brown found in the chamber liquid of some Nautilus specimens¹⁰.

A long column of air was trapped in a high pressure nylon tube and forced into the siphuncular tube segments under 103 m head of water. No bubbles of air appeared on the surface of the siphuncular tube, and the water-air interface in the nylon tubing did not move during a period of 10 min. Thus, when the siphuncular tube is moist as it is in life, no gas will pass through. This finding, along with the invariably low gas pressure encountered in *Nautilus* shell chambers^{9,10}, seems to discount the hypothesis that the siphuncle generates gas into the shell chambers in order to balance the hydrostatic pressure. Thus it would seem that the only way gas can enter the chambers is by simple diffusion10.

With no assistance from gas pressure, the shell, including the siphuncular tube, must withstand the considerable hydrostatic pressures encountered by Nautilus at depth (up to 900 p.s.i. at 600 m). Denton and Gilpin-Brown proved that the shell is strong enough, and also found that two pieces of siphuncular tube could resist a tensile stress of 500 p.s.i. (ref. 10). This latter test was inconclusive, however, because the pieces of siphuncular tube had been in formalin for 3 yr, and the direction of stress was different from that experienced in a live Nautilus. To determine the strength more realistically, a hydraulic jack was used to force sea water into the five segments previously tested, until the siphuncular tube ruptured. Failure, under a head of 480 m, was at the artificial interface between 'Araldite' and the siphuncular tube, the remainder of the siphuncular tube being even stronger. Thus the siphuncular tube seems able to withstand the full hydrostatic pressures encountered by Nautilus.

We thank Mr V. C. Barber, of University College, London, for lending the fresh *Nautilus* shells, Mr Neil Bass, of Queen Elizabeth College, for analysing the salinity of the inflow and effluent liquids, and Mr Frank Cawley for setting up the pressure apparatus.

Effect of Exercise on the Thyroid Gland

WHILE testing the hypothesis that exercise increases the rate of renewal of thyroidal iodine in the rat we found that the total amount of iodine in the thyroid gland depends on activity (exercise). Usually a month or more is necessary1 to replace completely the iodine in the thyroid gland so that the total can be estimated by the technique of isotopic equilibrium2,3, and we assumed that if rats were exercising the increased expenditure of calories would be associated with an increased utilization of dietary iodine for the production of thyroid hormone, which would in turn lead to an increased turnover of iodine in the thyroid and a decreased isotopic equilibration period. The experimental results did not confirm this, but they did reveal that the exercising rats stored only about half as much iodine in the thyroid as did the nonexercising controls.

In the initial test, sixteen male Wistar rats weighing 125-150 g were placed in small individual wire cages, eight of which were equipped with revolving activity drums and cyclometers. The rats were fed a low iodine diet and iodine-129 was added to the water supply so that each rat received about 10 µg of iodine/day. After 28 weeks, iodine-125 was added to the water supply, and 2 weeks later the rats were killed. The thyroids were removed and their iodine-129 and iodine-125 radio-activities compared with that of a standard sample of the radioiodinated water supply. Total thyroidal iodine and the percentage of iodine renewed in the last 2 weeks were calculated. Live body weights, iodine consumption and number of revolutions of the activity drums were recorded weekly during the period of 30 weeks.

In the second test, sixteen male Wistar rats weighing about 100 g each were placed in the small cages. Again eight of the cages were equipped with activity drums. A low iodine diet was given and iodinated water labelled with iodine-125 was supplied so that each rat received about 5 µg of iodine/day. After 5 weeks the rats were killed and the total amount of iodine in their thyroids was determined by comparing the iodine-125 radioactivity of their thyroids with that of standard samples of the radio-iodinated water supply. Numbers of turns of the activity drums had been recorded weekly for those rats in the exercise cages.

In the first experiment, non-exercising rats had an average of 9.0 ± 0.9 µg of iodine in their thyroids; the exercising rats had an average of $5.8 \pm 0.5 \mu g$ of thyroidal iodine. The percentage of the thyroidal iodine renewed in 2 weeks was 62.5 ± 1.6 for the non-exercising rats and 59.8 ± 2.7 for the exercising animals (Table 1).

In the second test, the non-exercising rats had an average of 20.0 ± 1.9 µg of iodine in their thyroids compared with $9.9\pm1.2~\mu g$ in the exercising group. The results are summarized in Table 2.

In both experiments, the non-exercising rats had, on average, approximately twice as much total thyroidal iodine as the exercising rats. On the other hand, a significant difference in the rate of renewal of thyroidal

iodine was not found. When both sets of data are combined and tested for a correlation between the amounts of exercise and the amounts of iodine in the thyroid, a negative correlation (0.025 < P < 0.05, statistical test based on Spearman's Rand correlation coefficient) is found. It is concluded that the more rats exercise the less the storage of iodine in the thyroid gland.

Previous studies have not led to a general concept of the role of the thyroid gland in exercise. Ricter⁴ showed that thyroidectomy produced a decrease in spontaneous activity in rats which was restored to pre-thyroidectomy levels by the administration of thyroid hormone. The feeding of thyroid hormone to rats, however, does not seem to increase spontaneous activity (ref. 5 and unpublished results of C. E. Easley and myself). Muscular exercise has been reported not to increase the rate of degradation of thyroid hormone^{6,7}, but Escobar del Rey and Morreal de Escobars did find that radiolabelled thyroxine disappeared more quickly in rats when longer periods of exercise were employed. Carriere and Isler⁹ found that forced muscular exercise as well as the psychological stimulation resulting from frequent changes of housing prevented the stimulation of the thyroid gland of mice caused by a diet deficient in iodine.

Previous studies have been handicapped by the superimposed effects of stress. Bogorock and Timiras¹⁰ and others11 have suggested that exercise experiments have antagonistic effects on the thyroid. The increased metabolism could cause a stimulation of the thyroid while the stress associated with the forcing of the exercise would tend to depress thyroid function. Brown-Grant et al.12 found that depressed thyroid function is a general response to stress in animals, but Korn¹³, on the other hand, found that the response to stress, as indicated by condition activity depression, is not affected by the thyroid gland.

^{*} Standard error of the mean.

In this experiment, stress is not involved because the exercise is spontaneous and the treatment of the exercise group is no different from that of the non-exercise control group. The data can be interpreted in two ways. Either thyroid activity is depressed as a result of the exercise6,9, or the utilization of thyroid hormone is increased so that more dietary iodine is converted to circulating hormonal iodine and less to stored iodine. I prefer the second explanation. It has long been known that decreased or absence of thyroxine is associated with a decreased utilization of oxygen and decreased energy exchange in respiring tissues14. Perhaps the converse is also truethat is, with the increased expenditure of energy and associated increased respiration there is an increased utilization of the thyroid hormones. This is consistent with the suggestion that activity of the thyroid hormones is associated with their metabolism. Thus, at a given steady state of iodine metabolism, exercising animals will not be able to store as much hormonal iodine as nonexercising animals.

The statistical testing was done by Dr Richard Royall of the Biostatics Department. This research was sponsored by the US Public Health Service.

Obligate Cation Exchanges in Red Cells

Coupling between the movements of sodium out of, and potassium into, human erythrocytes was discussed some time ago1. Although the concept of coupling between the active movements of sodium and potassium ions has been widely accepted^{2,3} it has been less usual to regard the down gradient "leak" movements as coupled. The stoichiometry of the active process met the difficulty that more sodium ions are extruded than potassium ions gained. To maintain electro-neutrality some other ion must move in association with potassium and sodium ions; this process has been somewhat neglected.

Results recently obtained by exposing erythrocytes to specific inducers of cation permeability such as valinomycin, gramicidin or nigericin provide evidence that the outward movements of cations down gradients are linked to contrary inward movements of other cations or protons. Participation of the latter largely explains the non-equivalence between movements of sodium and potassium ions and can account for the differing ratios of sodium to potassium ions obtained in different conditions.

Chappell and Crofts4 applied gramicidin to red cells in a choline and sodium salt medium and obtained internal concentrations of sodium ions greater than those outside at the expense of the depletion of the content of potassium ions. They also observed a shift of protons from the medium into the cells.

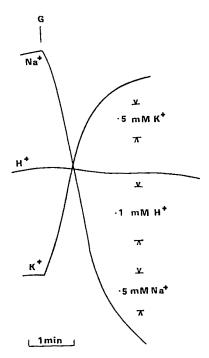

Fig. 1. Exchange between internal sodium ions and external potassium ions caused by grumicidin B (G) at 0.2 $\mu g/ml$, applied to a suspension of dog erythrocytes in 300 mmolar sucrose, 30 mmolar potassium chloride and 20 mmolar tris-chloride. The changes in the concentrations of sodium, potassium and hydrogen ions were monitored by ion-specific electrodes; movement from cell interior to solution is shown by a downward deflexion. Concentration of red cells was 0.042 ml. cells/ml.

There is a parallel between these cation exchanges in which the discharge of one gradient (that of potassium ions) sets up another (of sodium ions) and Rosenberg and Wilbrandt's induction of uphill transport of one sugar at the expense of counterflow of another with which the cells had been previously loaded.

The rapid ion exchanges induced by gramicidin can be illustrated with recordings obtained with ion specific glass electrodes (Fig. 1). With low concentrations of gramicidin (0·2 µg/ml.) there is little shift of pH (Fig. 1), but after addition of 1 µg/ml. of gramicidin the analyses of samples taken after 2–3 min showed that part of the emerging cation was replaced by protons. The figures in the first line of Table 1 show discharge of potassium ions from human erythrocytes setting up a gradient of sodium ions and those in the second line show discharge of sodium ions from dog erythrocyte setting up a gradient of potassium ions.

The results with the higher concentration of gramicidin show that proton movements cannot be neglected and the use of nigericin to increase permeability produces a more extensive cation for hydrogen ion exchange. Figure 2 illustrates the time course of this process, which is accompanied by some cation exchange as shown by the analyses in the third and fourth lines of Table 1. The cation exchange is sufficient to produce an outward gradient of the original extracellular cation, and a factor contributing to this is the shrinkage which accompanies the cation for proton exchange.

The requirement for another positively charged ion to replace the cell's potassium ions if it is to be discharged is also exposed by tests with the two agents valinomycin and trifluoromethoxy carbonylcyanide phenylhydrazone (FCCP). Valinomycin specifically increases permeability

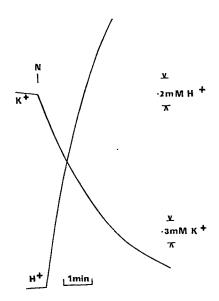

Fig. 2. Exchange chiefly between internal potassium ions and external protons caused by nigericin (N) at 0.5 μ g/ml. applied to a suspension of human erythrocytes in 300 mmolar sucrose, 10 mmolar sodium chloride and 20 mmolar *tris*-chloride. Cell concentration was 0.042 ml. cells/ml. of suspension.

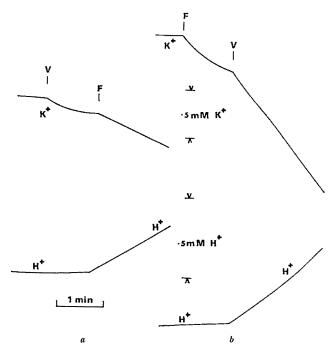

Fig. 3. Exchange between internal potassium ions and external protons caused by simultaneous presence of valinomycin (V) at 0-4 μ g/ml, and FCCP (F) (0-5 μ molar and 2-5 μ molar in a and b, respectively) applied to a suspension of human erythrocytes in 300 mmolar sucrose, 10 mmolar sodium chloride and 20 mmolar t16-chloride. Cell concentration was 0-045 ml, cells/ml.

of phospholipid bilayers to potassium ions and similar ions6 while FCCP produces a specific permeability to hydrogen ions7. Either agent when applied to a suspension of human erythrocytes in sucrose and sodium chloride causes only a limited loss of potassium ions, but when the second of the two agents is added a sustained exchange of potassium ions for hydrogen ions proceeds (Fig. 3). This resembles a result obtained with lipid micelles by Chappell and Haarhoffs in similar conditions.

Evidently in the evaluation of the stoichiometry of ion movements, the participation of protons must be taken into account. When metabolic acid is being produced, some of the protons can be used to replace sodium ions which are extruded and this in turn would account for the observed shrinkage. The obligate nature of the cation exchange, whether during energy-linked movements of sodium and potassium ions against their gradients, or when at least one cation is discharged down a gradient, shows that any chloride ion in the system does not act as a co-ion to accompany a lone cation. In other words, the anions do not shint the forces operating to accumulate one cation or proton as another cation emerges from what behaves as an internal cation exchanger. An agent which reduces the energy requirement for cations to enter the membrane material can accelerate movements in both directions, whether active or passive, as valinomycin does when applied to mitochondria. agent which also provides proton permeability in addition to that for alkali cations tends to discharge cations, as nigericin does when applied to mitochondria

Possible Mechanism for the Endocrine Control of Breeding in a Cirripede

THE breeding of the barnacle Balanus balanoides (L.) is controlled by light and temperature; a temperature below a critical value of 10° C and a light periodicity of less than 12 h/day are necessary before the barnacle will breed 4-8 weeks later. As part of the cyclic activity of the oviducal glands during the natural breeding phase of B. balanoides 2-3 weeks before fertilization an elastic sac is formed within each gland2 which envelops the eggs as they pass down the oviduct, forming a membrane binding the egg mass together.

A series of experiments was carried out in this laboratory to determine the influence of light and temperature on the state of the nervous system and glands associated with breeding. This communication describes the effect of these exogenous factors on the oviducal gland.

A population of B. balanoides was brought into the laboratory at the end of July 1965; from their size they were at least second-season specimens, with well developed ovaries and testes. They were kept in flowing sea water at temperatures between 15° and 20° C and were exposed to artificial light between 0800 h and 1730 h daily. On September 29 two parallel groups of barnacles were transferred to a low-temperature room (4° C), where one group was exposed to constant illumination and the other to constant darkness. The populations were sampled at regular intervals and a histological study was later made of these specimens. The barnacles kept in cold, dark conditions had bred by December 8; those in cold, light conditions had not. Breeding had not occurred in the second group by January 17, 1966, when they were transferred to dark conditions in the low-temperature room. Breeding occurred on February 17.

The results of the histological study of the oviducal glands of the two groups are given in Table 1, which shows the presence or absence of the elastic sac usually secreted by the oviducal gland. Constant light conditions had obviously inhibited the formation of the elastic sac produced by the barnacle under natural breeding conditions.

Table 1. ELASTIC SAG FORMATION IN OVIDUCAL GLANDS OF BARNACLES KEPT UNDER LIGHT AND DARK CONDITIONS IN A LOW-TEMPERATURE ROOM

December 8	${ m Light \atop Dark}$	Absent Egg mass

Table 2. ELASTIC SAC FORMATION IN OVIDUCAL GLANDS OF BARNACLES

TRANSPERRED	TU	COTDIDVER	CONDITIONS ON	JANUARY	0	
Date			State of	gland		
January 6 January 12 January 19 January 26 February 3			No sac Secretion Sac being form Sac Egg mass in m		ty	,.

Another series of barnacles from the original population was kept in a warm laboratory in an aerated static-sea water tank until January 6. The temperature of the sea water varied between 16° and 20° C and the barnacles were illuminated daily from 0800 h to 1730 h. Breeding had not occurred by January 6 and the elastic sac had not been produced in the oviducal glands. The barnacles were then placed under dark conditions in the low-temperature room and sampled at intervals. Breeding had occurred by February 3. Table 2 shows the conditions of the oviducal glands in these barnacles.

These results show that the effect of light on the breeding of B. balanoides is, in part, to inhibit cyclic activities of the oviducal gland. This is unlikely to be a direct photo-effect on the gland, so it is probable that there is inhibition from the photo-receptors and nervous system. A possible mechanism is indicated by the observation that when barnacles are illuminated the photo-receptors generate a sustained depolarizing potential which inhibits second-order neurones in the supra-oesophageal ganglia; this inhibition is removed when the illumination is stopped3. There may be a neurosecretory role in this control, for neurosecretory fibres have been reported in the median photo-receptor nerve of Balanus cariosus⁴ and I have found neurosecretory cells in the sub- and supra-oesophageal ganglia of B. balanoides.

The role of temperature in the inhibition of breeding of B. balanoides is uncertain. The absence of elastic sac formation in the barnacles kept until January 6 under a less than critical light exposure, yet in warm conditions, indicates that temperature has an inhibiting effect on

The control mechanism for oviducal gland secretions. this could be analogous to that in the Cecropia silkworm Hyalophora where there is a low-temperature requirement (6°-15° C) before neurosecretory cells will initiate the termination of pupal diapause5.

At present little is known about endogenous control systems in Cirripedia. My observations indicate a possible control mechanism for breeding in B. balanoides which would bring cirripedes into line with the general pattern of endocrine control in Arthropods and provide a basis for further experiments.

Monosynaptic Stochastic Stimulation of Spinal Motoneurones in the Cat

THE artificial nature of a synchronous afferent volley was pointed out many years ago1 and, although neurophysiological knowledge has been considerably advanced by use of the synchronous volley technique, it has definite limitations in providing a full understanding of reflex mechanisms in the intact animal. Each annulo-spinal ending in a muscle under tension discharges in a quasiperiodic manner, and the differing stretch thresholds in these receptors² cause the average discharge frequency of each ending to differ. The timing of the initiation of impulses in one ending will be statistically independent of

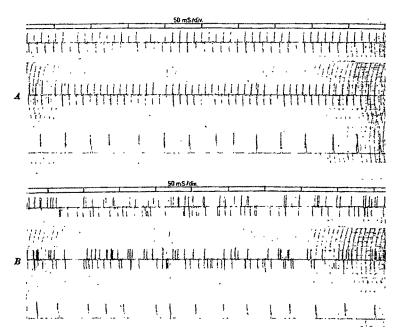

Fig. 1. A, Pen recording showing four asynchronous trains of periodic stimuli, each at a nominal frequency of 100/sec, and the simultaneous discharge in a ventral root filament. Individual stimulus strengths were confined to less than max. GpI, and adjusted such that simultaneous stimuli processes on at least three separate pathways were necessary for the cell to discharge. Stimulus impulse deletions indicate where two combined stimulus impulse trains drift into phase. B, Four independent Poisson or random stimulus impulse trains, with mean impulse rates approximately 100/sec, applied in place of the four periodic processes in A. All other stimulus and recording conditions are identical to those in A.

the times of occurrence of impulses in other endings. The convergence of these asynchronous impulse patterns onto a particular motoneurone represents a situation very different from that of synchronous stimulation and introduces the effects of temporal summation. If the object of the experiment is to establish relationships between afferent and reflex impulse patterns, natural stimulation by stretching muscle has severe limitations, because the temporal impulse patterns arriving at a particular motoneurone cannot be obtained. In the experiments described here, an attempt has been made to overcome this problem while retaining a stimulus which is physiologically realistic.

All experiments were performed on cats which had been made spinal under ether anaesthesia. Many branches of posterior biceps-semitendinosus or gastroenemius-soleus muscle groups were prepared for stimulation by fine dissection down into the muscle. A motoneurone responding monosynaptically to synchronous stimuli on either of these nerve groups was isolated by way of a ventral root filament. Only afferent branches which caused a detect. able depolarization of the motoneurone were used in the experiment. These branches were found by the presence of a reflex spike when the depolarization caused by stimulation of the branch under study was added to a slightly subthreshold depolarization produced by synchronous stimulation of other effective branches. Each useful afferent branch was then separately stimulated by either a periodic or random pulse process such that the stimulus processes for each nerve branch were asynchronous. Stimulus strengths were usually much less than maximum GpI and were adjusted to ensure that at least two separate afferent fibre groups required simultaneous stimulation to produce sufficient summation to evoke a reflex discharge. Stimulus frequencies were varied between 10/sec and 200/sec. The individual stimulus frequencies were adjusted to be within ± 10 per cent of a nominal stimulus frequency.

The nature of asynchronous or stochastic stimulation

is illustrated in the pen recordings in Fig. 1. These were obtained by replaying tape recorded stimulus processes and ventral root discharge at a reduced speed and combining two stimulus trains onto a sing'e pen, using polarity to distinguish between them. Fig. 1A shows the effect of applying four trains of periodic stimuli, of slightly different frequency, and randomly phased to four afferent nerve groups of the cell the discharge of which is being recorded. In the experiment recorded in Fig. 1B, the same cell was subjected to stimulus processes of random or Poisson type with the same average stimulus rate and which were delivered at the same stimulus intensity as in the previous case. In both cases, temporal and spatial summation combine to discharge the cell, and the discharge is noticeably regular in its interspike interval duration. A slowly discharging cell does not have the same regularity.

The long term discharge response of motoneurones stimulated with a suddenly applied and maintained stochastic stimulus shows considerable variation. Recordings from the same motoneurone pool with constant stimulus conditions provide discharges which vary from extremely phasic to extremely tonic in nature, with all intermediate combinations of these discharge characteristics. These results suggested a continuous distribution between tonic and phasic properties within a functional motoneurone pool, as other investigators^{3,4} have recently suggested, rather than a distinct division into tonic and phasic motoneurones.

Motoneurones which discharge tonically were stimulated with a range of frequencies and the stimulus strengths were kept constant on all stimulated pathways. At least 60 sec of continuous recording was made at each stimulus frequency and the mean discharge frequency was calculated from the entire record. The relationship is shown in Fig. 2, where a curve has been drawn for periodic asynchronous stimulation and points are shown for the Poisson pulse rates which were available. This and other similar results indicate an approximately exponential relationship between the mean afferent and efferent frequencies in the afferent range of 30-120/sec (an important physiological range). Frequency limiting usually occurs at an efferent frequency of 10-15 impulses/sec and the afferent frequency at which this discharge rate occurs depends on the individual stimulus intensities. threshold is exceeded by three, but not two, afferent groups which have been simultaneously stimulated, the stimulus frequency is usually in the range of 100-120 pulses/sec. This frequency limiting has been a consistent finding with various electrical stimulation methods involving GpI fibres only^{8,7}. Frequency limiting has previously been ascribed to the effects of recurrent inhibition8. In this experimental arrangement, the motoneurones of the excited pool will excite Renshaw cells asynchronously and recurrent inhibition will be operative. experiments measuring frequency transfer characteristics before and after the infusion of dihydro-beta-erythroidine (hydrobromide) indicate that recurrent inhibition does not change the frequency at which limiting occurs. We believe that repolarizing current during "after hyperpolarization" and the depolarization limitations of the Ia afferent pathways are the principal factors in limiting the discharge frequency.

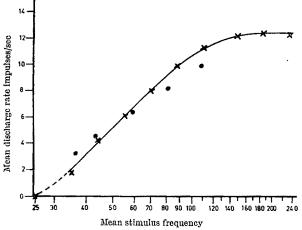

Fig. 2. Results taken from a unit responding tonically to stimulation of gastroenemius-soleus nerves. All branches of medial and lateral gastroenemius and soleus muscle groups were arranged on four separate stimulators. The stimulus strength on each was adjusted such that, at a nominal frequency of 100/sec for each stimulator, all but two combinations of pairs were effective in discharging the cell when asynchronous stimulation was applied from two stimulators at a time. Measurements were taken in order of increasing frequency, with a 3 min period without a stimulus between each record. No discharge was obtained at a mean stimulus frequency of 25/sec, which was the next available frequency below 35/sec. The discharge could have ceased at an intermediate frequency. There was no alteration in stimulus strength when Poisson stimuli were used. ×, Asynchronous periodic stimulation; •, Poisson stimulation.

The frequency transfer curve specifies the stationary transfer properties of a single monosynaptic reflex pathway with a fixed number of stimulated afferent fibres. A more complete description of the reflex pathway would be a family of frequency transfer curves with "recruitment" as a parameter.

The technique of stochastic stimulation offers a method of establishing reflex discharges from neurones excited by means of converging peripheral pathways in a controlled and approximately physiological manner. Modulation in the excitability of the neurone may then be quantitatively measured by changes in the discharge frequency of that cell. A precise knowledge of the afferent temporal patterns is also helpful in investigating input-output relationships.

Strychnine Block of Neural and Drug-induced Inhibition in the Cerebral Cortex

THERE have been conflicting reports about the actions of strychnine on cortical inhibitions. Inhibition of cortical neurones by direct cortical stimulation is resistant to strychnine^{1,2}. The "recurrent" inhibition of cortical neurones during stimulation of the pyramidal tract has been said to be both resistant to strychnine^{1,3} and antagonized by strychnine⁴⁻⁷.

This investigation of the actions of strychnine on neural and drug-induced inhibitions in the cerebral cortex was started when we realized that strychnine antagonized the depressant actions of noradrenaline and 5-hydroxytryptamine (5-HT) on neurones in the left precruciate cortex.

All experiments were performed on cats anaesthetized with nitrous oxide and methoxyflurane ('Penthrane', Abbott). Drugs were applied iontophoretically from five barrelled micropipettes, the central barrel of which was used for recording the extra cellular spike potentials of cortical neurones. A Hewlett-Packard electronic counter coupled to an ink-recorder was used to analyse the discharges of cortical neurones which were either spontaneous or evoked by L-glutamate. L-Glutamate pulses of 5-10 sec duration were repeated at regular intervals. Changes in cell excitability were assessed by comparing the spontaneous firing frequencies or those induced by L-glutamate, during and after the application of depressant compounds or during stimulation. The duration of inhibition evoked by direct stimulation was measured as the period of suppression of spontaneous or induced firing. Ipsilateral stimulating electrodes were placed in the lateral hypothalamus (All. 5, L4, D-3), mesencephalic reticular formation (A3, L3, D-1) and on the exposed pyramidal tract. A fine bipolar co-axial electrode was inserted directly into the precruciate cerebral cortex to a depth of 1 mm for cortical stimulation.

Strychnine was applied iontophoretically from a barrel containing 10 mmolar strychnine in a solution of 200 mmolar sodium chloride. When applied by currents of 20-50 n.amp, strychnine had a depressant action on neuronal activity. Firing induced by L-glutamate was

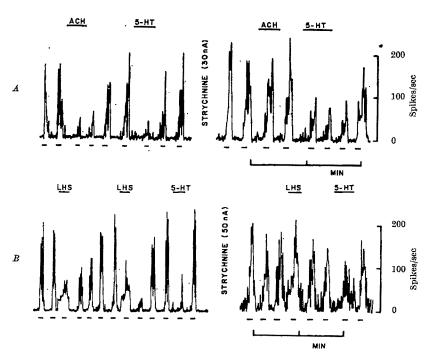

Fig. 1. A, Effect of strychnine (30 n.amp for 2 min) on the depression of L-glutamate (40 n.amp) firing by 5-HT (30 n.amp) and ACh (30 n.amp). B. Depression of L-glutamate (40 n.amp) firing by repetitive (10/sec, 6 V) stimulation of lateral hypothalamus and 5-HT (40 n.amp) was antagonized by strychnine (50 n.amp for 2 min). Applications of L-glutamate or 5-HT and ACh are indicated by horizontal lines below and above the records, respectively. Recording was interrupted during and for a period of 3 min immediately after application of strychnine

depressed for 2-3 min after strychnine application had Cell excitability was frequently enhanced after ceased. this.

The depressant effects of 5-HT, noradrenaline and acetylcholine (ACh) on cortical neurones have already been described⁸⁻¹⁰. On animals anaesthetized with nitrous oxide and 'Penthrane', all three compounds have potent depressant actions. 5-HT depressed 89 per cent of the 131 neurones tested, noradrenaline depressed 49 per cent of 43 neurones tested and ACh 32 per cent of 162 neurones tested. On many of these cells the actions of the depressant drugs could be reduced or abolished by strychnine. Examples of a reduction of depression by 5-HT and almost complete block of depression by ACh are shown in Fig. 1A.

Long lasting inhibitory effects of repetitive stimulation of pyramidal tract or reticular formation on cortical neurones which were also depressed by ACh have been described elsewhere¹⁰. Application of atropine or hyoscine to such neurones usually abolished the response to ACh and reduced or abolished the neurally evoked inhibitions. Strychnine has now been observed to have a similar effect on these inhibitions.

Destruction of tissue in the lateral hypothalamic nucleus is associated with a marked decrease in the concentrations of noradrenaline and 5-HT in the neocortex of cats11,12. It seems that cats have a monoaminergic pathway from the brain stem to the cortex through the medial forebrain bundle, which has been described in rats13.

Stimulation in the lateral hypothalamus evokes short latency negative focal potentials in the feline precruciate neocortex which seem to have a maximum amplitude between depths of 800-1,300μ. A short latency inhibition lasting 100-150 msec was also frequently observed. Less usual (in sixteen of the seventy-one cells tested) was a long lasting inhibition of firing, both spontaneous and induced by L-glutamate, which had a duration of up to 1 min after stimulation had ceased (Fig. 1B).

The short latency inhibition associated with stimulation of the lateral hypothalamus was, like the comparable inhibition evoked by direct stimulation. resistant to strychnine (see also refs. I and 2). On all occasions on which it was tested, however, strychnine abolished the long lasting inhibition evoked by stimulation of the lateral hypothalamus. An example of this is shown in Fig. 1B. Stimulation of the lateral hypothalamus (10/sec for 15 sec) greatly reduced the response of this cell to L-glutamate pulses, and 5-HT almost abolished the Strychnine (50 n.amp) was applied for 2 min and, when recording continued 3 min later, stimulation of the lateral hypothalamus had an excitant action and the depressant action of 5-HT was greatly reduced.

It is apparent from these results that strychnine depresses some synaptic inhibitions in the cerebral cortex and not others. In particular, the long lasting inhibitory effects of stimulation of pyramidal tract-reticular formation and lateral hypothalamus seem to be depressed while the relatively short inhibitory effects of stimulation of the surface and the lateral hypothalamus are unaffected. In a similar study of the effects of strychnine on the depression of Renshaw cells in the spinal cord. no antagonism between strychnine and noradrenaline was observed although synaptic inhibitions were reduced 14. In these experiments, the amounts

of strychnine used were not great enough to produce extracellular concentrations which alone reduced the sensitivity of Renshaw cells to excitants and this may be an explanation of the different results obtained. The full significance of these actions of strychnine on neural and drug-induced inhibitions has yet to be evaluated. The fact that strychnine will antagonize depressions produced by such disparate compounds as the monoamines and ACh, however, suggests that it may effect the membrane permeability changes induced by these compounds.

These results also support the idea that 5-HT and noradrenaline containing pathways project from the lateral hypothalamus to the cerebral cortex.

RADIOBIOLOGY

Suppression of Experimental Allergic Encephalomyelitis in Mice by Irradiation of the Target Organ

THE pathogenesis of experimental allergic encephalomyelitis (EAE) is not definitely known and yet it is frequently used as an experimental model for the study of autoimmune disease of the central nervous system. Waksman contends that the principal event giving rise to EAE after injection of the antigen is the passage of immunologically competent cells or histiocytes through small venules into the nervous system¹. These cells originate in the blood stream and are held responsible for the destruction of elements containing antigen in the central nervous system by an undefined mechanism. It has been found that EAE can be suppressed, either by generalized physical or chemical cytotoxic agents, or by destruction of the regional lymph nodes draining the inoculation site²⁻⁹. This communication reports the suppressive effect of localized irradiation of the brain in mice during the induction of EAE, and compares the effect with that of total body irradiation.

Random bred adult $BSV\tilde{S}$ mice from the mouse colony of Rockefeller University were used. The mice were sensitized by intraperitoneal injection of Haemophilus pertussis vaccine and 4 days later they were given an intradermal injection of mouse brain with adjuvant, which was repeated 10 days after the first sensitization. The mice were irradiated at intervals after the first sensitization, with varying doses administered to the total animal, to the head only or to the body only. A typical schedule of sensitization and irradiation is shown in Table 1. The techniques of sensitization and irradiation have been described in detail in previous publications^{10,11}. The irradiated animals were divided into two groups; one received a high dose (400 r. × 5) and the other a low dose (100 r. × 5). Among the controls used, some were sensitized and not irradiated and others were irradiated but not sensitized. All animals were killed 30 days after the first sensitization and their brains were removed for histological examination. The severity of the pathological change in the brain was graded from 0 (negative) to 5+ (marked positive). As a control for the effect of irradiation on immune reactions in mice, reciprocal skin homografts were performed in BSVS mice which were then given irradiation to the head only in the same schedule as that employed for the EAE animals. The lesions in the sensitized BSVS mice were those characteristic of EAE-infiltration of the meninges, ependyma and perivascular spaces with lymphoid cells¹². These were designated mild positive or 1+, positive or 3+ and marked positive or 5+. All the sensitized non-irradiated animals had such lesions, and these were predominantly 3 to 5+ in severity. Irradiation of the head only did not prolong the rejection times of reciprocal skin grafts in the $BS\,VS$ mice.

The results of total body irradiation, head irradiation only or body irradiation only at high irradiation dose (2,000 r.) are shown in Table 2 and the results of low irradiation dose are shown in Table 3. The lesions in the irradiated mice are usually predominantly mild (1 to 2+) as shown in Tables 4 and 5. The lethal effect of total body irradiation is easily seen. In the sensitized animals receiving 2,000 r. to body and head, six out of seventeen died before day 15, possibly too early for pathology of EAE to be evident. The deaths were probably caused by the effect of total body radiation.

Table 1.	SCHEDULE	OF SENSITIZATION-IRRADIATION EXPERIMENT
Day		Treatment
-4 0 3 7	•	H. pertussis vaccine intraperitoneally Mouse brain and adjuvant intracutaneously Irradiation treatment 1 Irradiation treatment 2

Table 2. EFFECTS OF HIGH IRRADIATION DOSE (2,000 r.) ON EAF IN MICE

Group	No. of mice	pathology per cent positive
Sensitized No irradiation	32	100
Sensitized Head irradiation only	38	63
Sensitized Body irradiation only	18	56
Total irradiation only	16	31
Not sensitized Head irradiation only	12	0
Not sensitized Body irradiation only	· 13	. 0

Table 3. EFFECTS OF LOW IRRADIATION DOSE (500 r.) ON EAE IN MICE

Group	No. of mice	pathology per cent positive
Sensitized No irradiation	32	100
Sensitized Head irradiation only	19	74
Sensitized Body irradiation only	20	65
Not sensitized Head irradiation only	8	0
Not sensitized Body irradiation only	8	0

Previous workers² have shown that excision of regional lymph nodes at any time in the first 2 days after sensitization prevented the development of EAE and there was a significant reduction even in animals whose nodes were not removed until 12 days after sensitization. Physical cytotoxic methods such as irradiation of the regional lymph nodes 4 days before sensitization also reduced the incidence of EAE while irradiation of other nodes or irradiation after sensitization had no effects. Whole body irradiation administered to rats before sensitization was effective in preventing EAE while irradiation after sensitization was not as effective. Mice

are sensitive to irradiation, and soon die when large doses are administered to the whole body. When irradiating the head alone, we took care not to produce necrosis of the pharynx and subsequent inability to eat and swallow. Two doses of radiation were selected in order to find a level which would be effective in suppressing EAE and yet would enable the mice to survive. At 500 r., more mice survived but there was a slightly higher incidence of positive lesions in the brains than when only the head was irradiated. By increasing the dose to 2,000 r., there were fewer brain lesions but more animals died from radiation sickness.

Chemical cytotoxic agents such as methotrexate, 6-mercaptopurine, corticosteroids and nitrogen mustard administered systemically have also been successful in various degrees in suppressing or preventing EAE4,5,7-9.

All these methods seem to be acting through a general suppression of the reticuloendothelial system and immune phenomena. There are obvious disadvantages in this and it was considered feasible to prevent EAE by action of immunosuppressive or cytotoxic agents aimed at the target organ or the brain itself. Neural tissue is very resistant to effects of irradiation while lymphoid elements are very sensitive. In previous experiments, the attempted immunosuppressive effect has been directed at the cellular or humoral sites which produce antibody. this study, the immunosuppression has been directed at the point of attack of the antibody or the target organ and a significant degree of suppression of EAE has been achieved. It would not be improper to conclude from these results that Waksman's theory is valid. The entrance of sensitized lymphocytes into the nervous system is impaired by irradiating the head which destroys these cells, and hence the disease is suppressed.

This research was supported by grants from the National Institutes of Health, US Public Health Service, and from the D. H. Goldman Research Fund.

BIOCHEMISTRY

Quantitative Evaluation of Tritium in Autoradiography and Biochemistry

TRITIUM emits 6-particles of such low energies that absorption even in very thin layers of organic matter has to be taken into account. Calculations of the absorption of β-particles within a layer in which tritium is incorporated and in a superimposed layer of organic matter are presented in this communication. For a biological specimen the absorption can be taken as proportional to density.

The emission spectrum of tritium was computed using a nuclear coulomb factor, F(Z, W), evaluated from the National Bureau of Standards tables1.

 $N(W) dW \propto F(Z, W) \cdot (W^2 - 1)^{\frac{1}{2}} \cdot (W_0 - W)^2 \cdot W \cdot dW$ where N(W) dW =the number in interval dW, $W = m/m_0$ for the electron, and W_0 corresponds to the maximum electron energy assumed to be 18 keV.

The average kinetic energy as obtained from this calculation was 5.7 keV, in agreement with the evaluation of Jenks et al.2, the spectrum having a peak at 2.3 keV (Fig. 1). This peak is close to the experimental and theoretical values of Curran et al.3. For electrons of these energies the ratio of energy loss by radiation to that by ionization is less than 2×10^{-4} . The percentage of the particles traversing a given thickness of material, and their emergent energies, can therefore be estimated using equations (2) and (3),

Range = $R(mg/cm^2)$ = 412 · $E^{(1\cdot265-0\cdot095\cdot\ln E)}$ (2)where E is the kinetic energy in MeV.

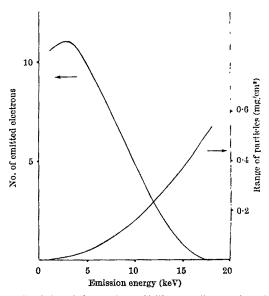

Fig. 1. The beta emission spectrum of tritium, and the range in mg/cm² of the emitted particles. The range shown is an average for particles of that energy.

Energy loss =
$$\frac{\mathrm{d}t}{\mathrm{d}s} = \frac{6.728}{W} \times \ln(W \times 17.33) \,\mathrm{keV}/\mu$$
 (3)

A series of calculations was made on an Elliott 803 computer for an evenly loaded layer of thickness L, covered by an unlabelled layer of thickness t (Fig. 2). For emission from tritium the percentage (P) of emitted particles reaching the surface and their energies were found (Fig. 3). For L < t/2 and $t < 3\mu$ a fit (within 2 per cent) to the curve is given by

$$P = \frac{1}{2}(48e^{-2\cdot3937t} + 51e^{-6\cdot115\sqrt{t}} + 0\cdot0058t^2 - 0\cdot0832)$$
 (4) t is in μ for material of density $1\cdot5$ g/cm³. If $t < 1\mu$, only the first two terms are significant. For thick, evenly loaded tissue (Fig. 4) the percentage reaching the surface is

$$\int_{t_1}^{t_2} P.dt / \int_{t_1}^{t_2} dt$$
 (5)

If the thickness is $T \mu$, this equals

$$P = \frac{1}{2T} \cdot \left| -20.04 e^{-2.3937t} - 16.68t^{\frac{1}{6}} \cdot e^{-6.115\sqrt{t}} - \right|$$

$$2.729e^{-6.115\sqrt{t}} + 0.0019t^3 - 0.0832t \begin{vmatrix} t_2 \\ t_1 \end{vmatrix}$$
 (6)

For $t_1 = 0$ and $T > 4\mu$ this reduces to $12 \cdot 15/T$.

These computed results for the percentage of β-particles emerging agree very well with the experimental results of Fitzgerald et al.⁴ for an aluminium absorber; the discrepancy is less than 3 per cent if "zero" absorber thickness is taken as corresponding to 0·004 mg/cm² of absorber. Maurer et al.⁵ plotted grain density against absorber thickness, and obtained a curve similar to the one in Fig. 4. Discrepancies between Maurer's curve and the one in Fig. 4 can be explained by the variation of grain yield with the energy of the emergent β-particle. Ada et al.⁶ measured the grain yield per emergent electron, using protein films of various thicknesses and of density 1·3 g/cm³.

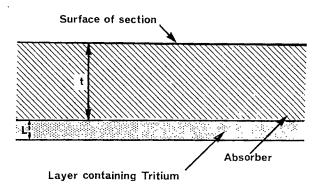

Fig. 2. Position of layer containing tritium within the section.

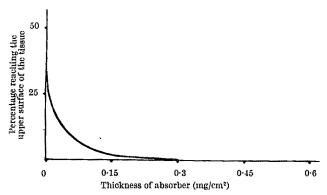

Fig. 3. Absorption, within the tissue, of the beta particles from a layer containing tritium. The thickness of this layer is 0.0075 mg/cm².

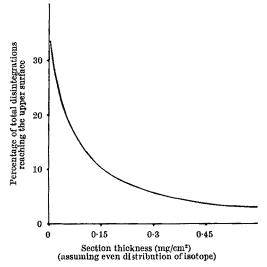

Fig. 4. Absorption, within the tissue, when the tritium is evenly distributed throughout the tissue.

They obtained values ranging from 0.28 grains/emergent electron for 0.5μ to approximately 0.65 grains/emergent electron at 5.0μ . Oja et al. measured the efficiency of K5 emulsion with sections of liver labelled with tritium. If a density of 0.75 g/cm² is assumed for their tissue, then their results are compatible with the values given for P in Fig. 4.

Maurer et al. found "infinite thickness" to be 0.05 g/cm^2 , that is less than 3μ of nucleoplasm, 2μ of cytoplasm and 0.6μ of nucleoli. In any section over which grain counts are made, therefore, small variations in thickness and the differing densities of the organelles, intercellular spaces, and so on will make quantitative evaluation of the tritium present impossible unless a direct tritium assay is undertaken.

Usually it clearly cannot be assumed that a tracer is evenly distributed in a specimen of even thickness of material of the same density. To estimate the influence of different distributions of tritium within a structure, such as a cell, it was assumed that the area was subdivided into ten equal areas and that the tracer was spread differently over these areas (Table 1). For example, if all the tritium was in a homogeneous layer 4μ thick the relative number of β-particles emerging towards an emulsion is 0.25, while if all the tracer is redistributed in a layer 0.25μ thick the relative yield is 1.52, that is six times greater. This apparently extreme and somewhat artificial model is encountered when interphase nuclei are labelled with tritiated thymidine and compared with the resultant labelled mitoses in squashes.

				Ta	ble 1				
Thickness (µ)	4	3	2	1	0.5	0.25			β/day

No. of areas	10 5 3 1 5 6 2	5 1 2 1	$\begin{smallmatrix}1\\2\\2\\2\end{smallmatrix}$	1 22 5 5	1 1 4	1	10 9·38 8·65 8·97 7·73 9·01 7·54 8·92	40 35 26·75 24·5 15 25 25 22	0·25 0·28 0·32 0·37 0·52 0·36 0·30 0·40
	1	1	1	1	1	1	1 0·97 0·93 0·81 0·57 0·38	4 3 2 1 0·5 0·25	0·25 0·32 0·46 0·81 1·14 1·52

Density of material assumed to be $1\cdot 0$ g/cm³. Concentration of tritium was assumed to be constant per unit density. An even layer of 4μ was assumed to have ten emerging β per day. If a thin layer containing tritium is covered by unlabelled tissue, the figures in the final column, (1)/(2), will be further reduced.

The grain yield per electron for energies from 0 to 18 keV is not known and a further correction may have to be applied before the results of our calculations can be converted to number of grains per disintegration.

to which the paramagnetic label is connected. When an iminoxyl free radical with a covalent bond is fixed in relation to the rigid tertiary structure of the protein by additional hydrophobic forces, the electron spin resonance spectrum is almost the same as the electron spin resonance signal of iminoxyl free radicals in rigid glasses. In other cases where there is a much greater mobility of a free radical attached to a protein, the electron spin resonance spectra can also be recorded.

In this work, we used a radical which attaches to SH protein groups with a high degree of specificity.

Electron Spin Resonance Investigation of Conformation Changes in Serum Albumin with the Help of Iminoxyl Paramagnetic Label

In iminoxyl free radicals¹ there is an odd electron localized usually at the nitrogen-oxygen bond. Because of the tensor anisotropy of dipole-dipole interactions and g-tensor anisotropy, the electron spin resonance spectrum of these radicals is quite sensitive to changes in the mobility of free radicals. The correlation time, τ , which can be found by width analysis of certain components of the electron spin resonance spectrum, is a characteristic of the tumbling motion rate of the free radicals².³. Using iminoxyl free radicals, with various substituents, reacting specifically with certain functional groups of proteins, it is possible to obtain free radicals labelled with macromolecules⁴.⁵

Because the correlation time of the free radicals is short in comparison with the rotation time of the protein macromolecules in solution, electron spin resonance spectra are essentially influenced only by the mobility of the free radical in relation to the protein molecule and the rate of mobility of the macromolecule chain fragment

One of its merits, extremely high stability, should be mentioned. It hardly changes its properties even after being kept in the open air for 2 yr.

The method of attaching a paramagnetic label to the molecules of bovine serum albumin (Koch Light Laboratories, Ltd.) was similar to that described by Griffith and McConnel⁵.

The electron spin resonance spectrum of the iminoxyl free radicals attached to molecules of bovine serum albumin (Fig. 1b) corresponds to a situation where a free radical is completely immobilized relative to the protein molecule. In protein globules the polypeptide chains are twisted in a very complex manner, and therefore the points of application of the additional bonds, immobilizing the paramagnetic label, are not necessarily in the same fragment of the polypeptide chain to which the free radical is attached. This is why it is quite possible that even small changes in tertiary structure of proteins may cause a relative rise in the mobility of the free radicals. It is known that to a certain extent the tertiary structure of proteins can be changed independently of the secondary structure. This can be seen in the action of polar solvents of the dioxane type compared with water. In proteins with many intermolecular sulphur-sulphur bonds, these polar solvents modify the tertiary structure, but do not

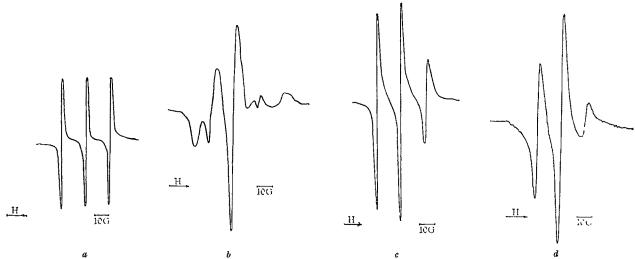

Fig. 1. a, Electron spin resonance spectrum of iminoxyl free radical in a water solution. b, Electron spin resonance spectrum of iminoxyl free radical attached to molecules of bovine serum albumin, 0.1 molar phosphate buffer, pH 6.8. c, Electron spin resonance spectrum of iminoxyl free radical attached to molecules of bovine serum albumin in a 10 molar solution of a urea. d, 50 per cent dioxane.

substantially affect the melting temperature of the α spiral. In 65 per cent dioxane the axis relation of serum albumin, a/b, increases three-fold compared with water solution of the protein. The percentage of spiral fragments increases by 1.5 at the same time.

Adding sufficient quantities of urea or dioxane to the solution of bovine serum albumin, labelled with free radicals, eliminates the wide signal of the immobilized paramagnetic label in both cases, and gives a narrower signal of a radical possessing relatively great mobility (Fig. 1c, d). Urea, however, destroys the secondary as well as the tertiary structure of bovine serum albumin and gives a greater growth of mobility of a free radical than the dioxane which chiefly modifies the tertiary structure of protein. τ , calculated for these two cases, was $1\cdot09\times10^{-8}$ sec for bovine serum albumin in 10 molar urea, and 2.04×10^{-4} sec for bovine serum albumin in a 50 per cent water-dioxane mixture.

 $ilde{\mathbf{A}}\mathbf{s}$ the relationship of narrow components in the process of denaturation did not change substantially and only the share of relatively free and completely immobilized free radicals did, the areas of the narrow and wide signals, S_2 and S_1 , respectively, can be easily determined, knowing their relationship to one of the corresponding components in the case of molecules of native and fully denatured bovine serum albumin.

The curve of urea denaturation of bovine serum albumin (Fig. 2) represents a typical melting curve of the protein

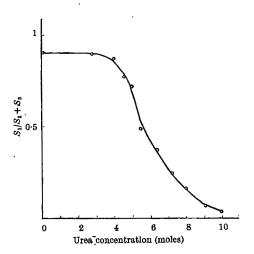

Fig. 2. Dependence of $\frac{S_1}{S_1 + S_2}$ on urea concentration.

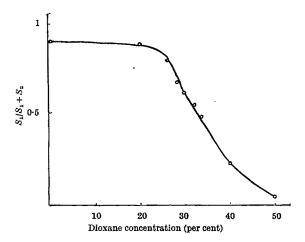

Fig. 3. Dependence of $\frac{S_1}{S_1 + S_2}$ on dioxane concentration.

secondary structure, and coincides well with the relationship obtained from the optical activity measuring method8,9.

The changes in the bovine serum albumin tertiary structure, affected by dioxane, take place in a rather limited range of concentrations of dioxane solution (Fig. 3).

The possibility of studying, with the help of a paramagnetic labelling, the changes in the protein tertiary structure when not accompanied by destruction of the secondary structure may be extremely useful, because the optical activity measurement method is not always applicable. The differences in correlation time for the bovine serum albumin, treated with urea and dioxane, should not be over-estimated, because it is not clear whether the lesser mobility of the iminoxyl free radicals in a water-dioxane mixture is caused by the withdrawing of the label from the point of application of the hydrophobic forces or by a changing flexibility in the fragment of the polypeptide chain to which the free radical is attached. When bovine serum albumin is denatured with urea both these effects must take place, but it is difficult here to estimate the role of each of them.

We thank A. M. Vasserman and A. Ya. Kulberg for their help in discussing the results of this work.

Relative Contribution of Carbon Dioxide Fixation and Acetyl-CoA Pathways in Two Nervous Tissues

CARBON dioxide fixation has been demonstrated in nervous tissue1-4, but its importance has not been assessed. By comparing the relative amounts of radioactivity incorporated from pyruvate-1-14C and -2-14C into aspartate and citrate, the relative contribution of acetyl-CoA and carbon dioxide fixation pathways in the conversion of pyruvate to citrate could be assessed.

Based on the two known pathways from pyruvate to citrate, and assuming an immediate randomization of the dicarboxylic acids (Fig. 1), C-1 of pyruvate would enter into citrate as C-1 and C-6 by way of carbon dioxide fixation and oxaloacetate. Both these carbons of citrate would be decarboxylated before reaching succinate in the tricarboxylic acid cycle (TCAC). C-2 of pyruvate would appear as C-2 and C-3 via this same pathway, and as C-5 via acetyl-CoA. All these carbons would be retained in citrate after the TCAC turned over once. Thus the specific activity of citrate from pyruvate-1-14C would represent only the carbon dioxide fixation or oxaloacetate pathway, and the difference between the specific activity of citrate from pyruvate-2-14C and pyruvate-1-14C would represent the acetyl-CoA pathway plus the recycling of

labelled citrate. In aspartate, a similar situation would be true, but the cycling aspect would seem to be emphasized because the acetyl-CoA from pyruvate-2-14C would not enter into aspartate directly. The possibility of the recarboxylation of decarboxylated C-1 of pyruvate should not be great, because carbon dioxide fixation would supply the same carbons of citrate and aspartate as of C-1 of pyruvate. Furthermore, the specific activity of this carbon dioxide would be greatly diluted by the internal non-radioactive carbon dioxide.

In the lobster nerves (Table 1), the specific activity of aspartate (2,430) from pyruvate-1-14C was much greater than the difference of the specific activities of aspartate (750) from pyruvate-2-14C and pyruvate-1-14C. The ratio was 0.3. This implies a low contribution of radioactivity by recycling of the TCAC, and pyruvate appears to be the primary precursor for aspartate and oxaloacetate. Similar results for citrate were 52,000 and 74,000, respectively, and the ratio was 1.4. This implies an almost equal contribution of radioactivity from pyruvate to citrate by means of the carbon dioxide fixation pathway and the acetyl-CoA pathway.

Table 1. Specific activities of aspartate and citrate derived from pyruvate-1- and $2^{-14}\mathrm{O}$

Tissue		Sub- strate m molar	μc./ μmole	Aspartate c.p.m./ µmole	Citrate c.p.m./ µmole
Lobster nerve	(A) Pyruvate-2-14C (B) Pyruvate-1-14C A-B	2 2	2·5 2·5	3,180 2,430 0·3	126,000 52,000 1·4

Rat striatum slices	(A) Pyruvate-2-14C (B) Pyruvate-1-14C	1·5 1·4	3·4 3·5	555,000 42,000	1,230,000 : 114,000
	$\frac{A-B}{B}$			12	10

Lobster nerve or rat brain striatum slices were incubated for 3 h at 15° C or 1 h at 37° C in their Ringer solutions, respectively^{3,2}. After incubation, the tissue was homogenized in trichloroacetic acid, and the protein precipitate was centrifuged off. Trichloroacetic acid was then removed from the supernatant with ether, and the aqueous solution, after removal of the ether, was charged on a 'Dowex-1'-acetate column's. Aspartate and citrate were cluted and their specific activities determined as described previously^{3,10}. Each value represents the average from three experiments.

In the slices of rat striatum, both ratios for aspartate and citrate remained high (Table 1). This suggested a relatively small contribution of the carbon dioxide fixation pathway as well as a relatively high rate of turnover of the TCAC. A greatly simplified estimation placed the ratio of radioactivity incorporation via the carbon dioxide fixation pathway to the acetyl-CoA pathway at approximately 1:10. This finding is in good agreement with those observations in vivo^{5,6} and

(2) Carbon dioxide fixation pathway with oxaloacetate as the intermediate and the randomization of the oxaloacetate carbon via the dicarboxylic acid shuttle.

indicates that the principal route of pyruvate metabolism in brain is via acetyl-CoA.

Oxaloacetate (or malate) has been generally considered as a key intermediate in the TCAC. The loss of carbons from the TCAC must ultimately be replenished by the carbon dioxide fixation reaction to yield oxaloacetate (or malate). In the lobster nerve, oxaloacetate was considered as the primary product of carbon dioxide fixation?. The magnitude of this reaction, as measured by the amount of radioactivity incorporated from carbon dioxide2 or pyruvate, might be related to a significant loss of TCAC intermediates and related compounds (unpublished). In contrast, in rat brain striatum slices, such loss appeared to be relatively small (unpublished) which agreed well with the low contribution of the carbon dioxide fixation pathway.

Although these two nervous tissues showed a quantitative difference in carbon dioxide fixation and the rates of turnover of the TCAC, the necessity of having carbon dioxide fixation to supply oxaloacetate for replenishing the loss of carbon skeletons during the operation of the TCAC remained the same. The low rate of carbon dioxide fixation in brain slices could account for the difficulty in demonstrating such a vital mechanism.

We thank Mr B. Arenberg for his technical assistance, Dr A. Lajtha for advice and the US Public Health Service for financial support.

Conditions of the Colour Change of Prodigiosin

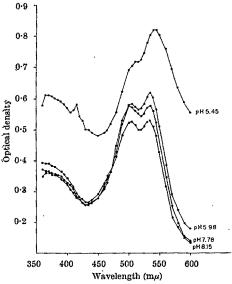

THERE have been several reports that prodigiosin, the pigment produced by Serratia marcescens, is red in acid solution with an absorption maximum at 535-540 mu but is yellow-orange in alkaline solution with an absorption maximum at 470 mm (refs. 1 and 2). This colour charge in strong acid or alkaline solution is recognized by anyone working with the pigment. The observation that the colour of a colony on an agar plate changes from orange to red when the pH, changing with growth, becomes more alkaline rather than more acid, and the report³ that eluates of single pink chromatographic bands show, on redevelopment, separation into both pink and orange bands, suggest that pH is not the only factor involved in the colour change of prodigiosin from red to orar ge.

To investigate this problem, prodigiosin was removed by a single extraction with an organic solvent from

.48-72 h cultures of a red pigmented strain of Serratia marcescens grown aerobically in trypticase soy broth or synthetic glycerol medium. Prodigiosin (30 ml.) was extracted from slightly alkaline cultures with 10 ml. of chloroform. No attempt was made to extract all of the pigment, but rather to remove as little as possible of other cell components; neither was any attempt made to purify the extract and it may have contained more than one pigment. The clear pink extract was distributed into tubes in 10 ml. quantities, and the solvent was removed by evaporation under a vacuum. Dried pigment was stored at room temperature; because of its instability and photosensitivity, it was not put into solution until minutes before use. Dried pigment was dissolved in 0.2 ml. of acetone and then water, buffer or acetone was added as desired. Usually prodigiosin was diluted 1:25 to give an optical density of between 0.5 and 1.0, using the Beckman \hat{DU} spectrophotometer; this is referred to later as a low concentration of pigment. A high concentration of pigment (1:10 dilution) gave an optical density reading greater than 1.0.

Aqueous solutions of high or low concentrations of prodigiosin in M/30 or M/150 phosphate buffer at different pHs are all red to pink in colour and have a peak at 535-540 mu with a shoulder, or distinct peak, at 500-505 mμ throughout a rather broad pH range. These peaks

can be seen in Fig. 1.

Aqueous solutions of a low concentration of prodigiosin in the presence of M/30 phosphate buffer at different pHs.

Large concentrations of prodigiosin in acetone in the presence of M/30 phosphate show red with a glass electrode reading of less than seven and yellow when the reading is greater than seven; acetone solutions containing high concentrations of pigment in the presence of M/150 phosphate are all yellow regardless of the pH of the buffer used. The colour of acetone solutions containing a low concentration of pigment with buffer of either strength remains in the yellow region. A scan of low concentration of pigment in acetone can be seen in Fig. 2. Although the glass electrode readings given are those taken before scanning, a continuous reaction seems to be taking place in the organic solvent and all readings tend to increase with time. At the end of the scanning procedure all values were 7-7.5, regardless of whether the initial adjustment was made with sodium hydroxide or with phosphate buffer. The change seemed to be related somewhat to the amount of prodigiosin used, suggesting that the pigment itself is contributing to this picture. The glass electrode reading of the acetone alone in these conditions remained constant,

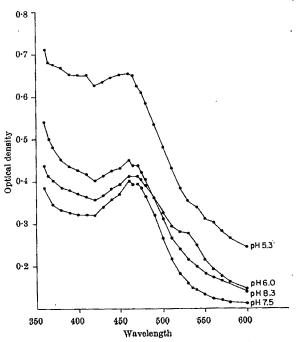

Fig. 2. Acetone solutions of a low concentration of prodigiosin in the presence of M/30 phosphate buffer.

These observations suggest that colour change in prodigiosin may be more closely related to its state of exidation or reduction than merely to pH. Certainly, there are several sites in this tripyrrole structure at which electron transfer could occur. To test this idea, aqueous and acetone solutions of prodigiosin in the presence of phosphate buffer (pH 7-7.5) were mixed with several known oxidizing or reducing substances. Results are shown in Table 1.

In aqueous solution, the only colour change came when known oxidizing agents were added to the pigment. There seems to be a complex interaction with permanganate which changes with time. A scan of the prodigiosinferricyanide mixture shows a flattening and broadening of the 535-510 mu peaks with only a very small peak appearing in the 470 mu region.

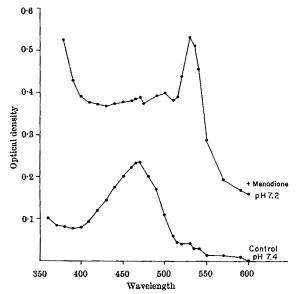

Table 1, COLOUR CHANGE OF PRODIGIOSIN AFTER ADDITION OF OXIDIZING OR REDUCING SUBSTANCES

	Colour of so addition of subs	electrode reading of acetone	
	Aqueous	Acetone	solution ·
Potassium permanganate (0.001 molar)	Orange	Yellow	7.5
Potassium ferricyanide (0-01 molar)	Yellow- orange	Yellow	7.8
Sodium dithionite (0.1 molar)	Pink	Pink	6.3
Ferrous chloride (0.01 molar)	Pink	Pink	6.5
Ferrous sulphate (0.01 molar)	Pink	Pink	6.5
Cysteine (0.1 molar)	Pink	Pink	6-8
NADH ₂ (5 mg/ml.)	Pink	Yellow	7.3
Menadione, bisulphite (0·1 molar)	Pink	Pink	7-2

Prodigiosin was dissolved in acetone, then diluted 1:20 in M/30 phosphate buffered water or acetone. The colour of the pigment in aqueous solution is pink and in acetone is yellow. To 1 ml. of diluted pigment one drop of the various solutions was added as indicated.

In acetone solution, the addition of sodium dithionite, ferrous compounds, cysteine or menadione resulted in a change of colour from yellow to pink. These reducing agents are acid in solution, and so they were brought to neutral pH before they were added to prodigiosin. In some cases, there was a decrease in the glass electrode reading after the colour had changed. These readings, however, were well within the range which may exhibit

the yellow 470 mµ maximum in other conditions (Fig. 2). The scan of the change after the addition of menadione given in Fig. 3 shows the shift of most of the major peak at 470-530 mµ with a smaller peak in this case at 500 mµ. The results are very much the same when iron salts are used. The menadione used was the bisulphite water soluble compound, and further experiments with unsubstituted oil soluble menadione are necessary to determine whether colour change in prodigiosin is also associated with the unsubstituted quinone.

Acetone solution of prodigiosin before and after the addition of menadione in the presence of M/150 phosphate buffer.

One interpretation of these results is that prodigiosin may exist in an oxidized (yellow) state or a reduced (red) state. The aqueous reduced form is not readily oxidized by the compounds used and there may be some breakdown of the pigment, for the absorbance curve is decreased and spread out. In acetone solution there seems to be direct electron transfer between acetone and prodigiosin. When conditions are carefully controlled so that acetone is in excess of pigment and electrons, pigment remains yellow or oxidized; on the other hand, when pigment or pigment plus electrons are in excess of acetone, there is no longer sufficient electron acceptor and the pigment remains in the red reduced state. Such an interaction between acetone and prodigiosin would seem to be a possible biological phenomenon. An enzyme catalysed acetone-NAD-isopropanol reaction was used for most accurate calculations of free energy change in reduction of NAD⁵.

Thus prodigiosin may readily accept and give up electrons in its environment, its colour being related to the electron intensity of the environment. This would the electron intensity of the environment. be compatible with a change in colour resulting from a change in hydrogen ion concentration; it would explain the orange to red colour change of colonies at a time when pH is rising, for reducing products of metabolism are also increasing. Such a mechanism could also account for the continued finding of some orange pigment from red chromatographic bands. In addition, this property would account for the repeated observation that this strain of organisms, in undisturbed deep liquid culture of synthetic medium in which the only carbon source is citrate, produces bright orange pigment at the surface but deep red-purple pigment at the bottom of the culture. The pH throughout the culture is considerably greater than seven at all times, but it is well known that there is more of a reducing environment at the bottom of a deep culture than at the surface.

If prodigiosin can act as an auto-oxidizable electron acceptor, then perhaps it plays a part in the respiration of the organism; this remains to be examined carefully. EMMA G. ALLEN

Stable Agar by Gamma Irradiation

DRY agar slowly deteriorates during storage, probably because of the degradation partly inherent in it and because of impurities which have not yet been identified, but processing stages designed to reduce sulphate2 and nitrogen seem to increase its stability. Until recently it has been the practice to extract agar from seaweeds immediately after collection. Recent experiments carried out in this institute to determine the effect of gamma radiation on dry seaweeds have led to some interesting observations which are reported here.

Samples (5 g) of various dried (100° C) red seaweeds (22 mesh) collected from the Saurashtra coast were sealed in 'Pyrex' tubes (15×100 mm) and exposed to a 1,000 c. cobalt-60 γ-source for low doses of 0.9-6.4 × 104 r./g. The agar was extracted from these samples in the way we have described before3, and the gel strengths were determined immediately and after various periods of storage. The results obtained, which are shown in Table 1, have led us to the following conclusions. (a) The quality of gel produced increases with dose in the low dose range up to a critical dose and this dose differs from species to species. (b) The instability of agar observed with the various species when stored for up to 2 months is not seen in any of the species which receive gamma irradiations. Furthermore, the effect of gamma radiations—in addition to stabilizing the agar—is to enhance the gelling power which remains steady at that value during the whole period studied. The results can be explained on the basis that the sulphate content in the agar molecule is reduced on irradiation which may result in an increased stability of agar on storage3.

Autoradiographic Detection of Reactive Protein-SH and its application to Anuran Haemoglobin Chains

THERE is a need for a simple method of detecting reactive sulphydryl groups in proteins and polypeptides after separation by zone electrophoresis. Most of the methods for detection and measurement of reactive sulphydryl groups are ultimately based on spectrophotometric measurements and only suitable for the sulphydryl groups of proteins in solution. An alternative method for the detection and comparison of the relative sulphydryl content of electrophoretically separable components of a mixture of polypeptides and/or proteins has been devised. This method which eliminates the need for previous isolation and purification of the protein mixture is based on autoradiography of mercury-203 bound to sulphydryl groups. We report here its application to several proteins with a known sulphydryl content and its use to show the absence of these groups in all tadpole haemoglobin chains and their presence in both chains of several frog haemoglobins.

The conditions used for radioactive labelling of proteins or polypeptide sulphydryl groups by reaction with chlormerodrin containing mercury-203 can be varied to suit most electrophoretic systems. Thus low pH and high concentration of urea were employed in these experiments to produce haemoglobin (Hb) chain separation and expose the maximum number of sulphydryl groups. After the addition of chlormerodrin*, the buffered protein solution was allowed to stand for several hours to permit the following reaction

R—²⁰³HgCl+HS—Protein — R—²⁰³Hg-S—Protein where

$$R = NH_2 - C - NH - CH_2 - CH - CH_2 - CH_3 - CH_3$$

After electrophoresis on starch gels, nigrosine or amido black was used to stain for protein. Protein bands which bound mercury-203 were detected by autoradiography. Fig. 1A shows the results obtained using this technique on human HbA, ribonuclease, twice crystallized ovalbumin and insulin. Fig. 1B indicates that ribonuclease and insulin, both of which have disulphide bonds but no free sulphydryl groups, did not bind mercury-203 in these

*We have found evidence for the instability of chlormerodrin in the conditions of starch gel electrophoresis (pH about 2.3). This instability did not interfere with this method, for the protein patterns obtained from electrophoresis of frog or human haemoglobin with or without the addition of chlormerodrin were the same. When chlormerodrin is broken down at low pH, the final product would be protein-8-Ha-Cl. The formation of dimers of the type protein-8-Hg-S-protein was apparently not significant in the presence of the 0.32 normal formic acid with 0.03 normal hydrochloric acid buffer used.

Table 1. BINDING OF MERCURY-203 BY PROTEINS TREATED WITH LABBILED CHLORMHRODRIN

Protein (purity)	Binding of mercury-203	Maximum No. of sulphydryl groups* (ref.)
Frog Hb (see Fig. 2)	++	8-10 (14)
Human Hb (whole haemolysate)	+ +	6 (14)
Ovalbumin (2x crystalline)	++	5 (6)
Aldolase [(NH ₄) ₂ SO ₄ suspension]	++	28 (14)
Cytochrome c (horse heart)	+	0 (1)
Ceruloplasmin (crystalline, human)	+	1 (15)
Mercaptalbumin (crystalline, human)	Trace	0-1 (2)
Bovine albumin (crystalline)	Trace	0-1 (2)
Tadpole Hbs (see Fig. 2)	Trace †	0-1 (14)
Ribonuclease (crystalline)	Q	0
Insulin (amorphous)	0	0
Sperm whale metmyoglobin	0	0

Abbott Laboratories Neohydrin-203 was used; this is chlormerodrin or 1-[3-(chloromercuri)-2-methoxypropyl]-urea containing mercury 203. Sperm whale metmyoglobin was given by Dr F. R. Gurd.

O, No exposure; trace, slight exposure; +, definite exposure; ++, very dense exposure of Kodak royal blue X-ray film in 24 h by the mercury-203 bound to protein. Approximately 5-20 µg of each protein at pH 2-3 in 6 molar urea was treated with excess chlormerodrin containing mercury-203 for 8-10 h before electrophoresis on starch gels.

* Maximum number of sulphydryl groups assumes complete dissociation into chains or sub-units in 6 molar urea, pH 2·3, used in the starch gel electro-

† Due to non-haem proteins.

conditions. HbA and ovalbumin contain free sulphydryl groups and showed positive binding of mercury-203. Table 1 shows the additional qualitative results obtained with several proteins and indicates good agreement between the ability to bind mercury-203 and the sulphydryl content reported in the literature. The data in Table 1 were obtained from several acid-urea-starch gels in conditions which should result in the exposure of most, if not all, reactive sulphydryl groups. Human haemoglobin has only two reactive sulphydryl groups at neutral

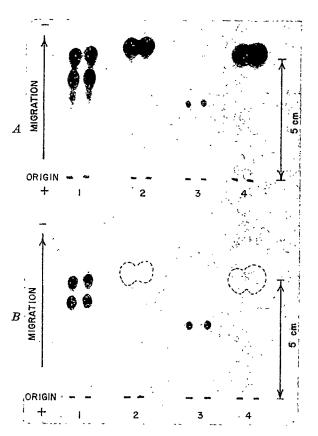

Fig. 1. A, Starch gel electrophoresis, pH 2·3, with formate: hydrochloric acid buffer, 6 molar urea, amido schwarz stain: (1) human HbA; (2) ribonuclease; (3) twice crystallized ovalbumin; (4) insulin. Samples 1, 2 and 4 were from a single gel and sample 3 was from a different gel run in the same conditions. B, Autoradiographic detection (X-ray film) of mercury-203 bound to sample shown in A. Broken lines indicate areas containing protein but no radioactivity. Note lack of binding by ribonuclease and insulin which contain disulphide but no sulphydryl groups.

pH, but when the chains unfold, four more groups are exposed². Disulphide bonds apparently do not bind mercury-203 in these conditions as shown by the negative results for insulin and ribonuclease in Fig. 1. An apparent exception is cytochrome c, which is reported³ to have both sulphydryl groups bound to vinyl side chains of the haem group. This binding is evident during starch gel electrophoresis of horse heart cytochrome c where the red colour remains associated with the protein. (Electrophoresis of haemoglobin in these conditions results in the removal of haem which then stays near the origin.) The bonds to the haem group of cytochrome c may have been partially broken to allow some binding of mercury-203.

Extensive differences in the molecular properties of tadpole and frog haemoglobins have raised the question of the presence of a chain in common between these two forms and analogous to the common α chain of adult (HbA) and foetal (HbF) human haemoglobins⁴⁻⁶. Baglioni and Sparks⁷ compared the peptide chains of tadpoles and frog globins using starch gel electrophoresis at low pH in 8 molar urea and found only one of similar mobility in both forms. DeWitt and Ingram⁶ have reported the occurrence of two N-terminal acetylated chains in the major haemoglobin of both tadpoles and frogs but have not determined the identity of the N-terminal amino-acid.

They report that the non-acetylated N-terminal amino-acids were glycine in the frog and valine in the tadpole. Herner and Riggs, were unable to detect a hybrid of haemoglobin after mixing tadpole and frog haemoglobins; if they had a chain in common, no hybrid would have been formed. If the two haemoglobins, however, had a different chain with similar mobility (in the experimental conditions), then any hybrid formed would have been undetectable. Thus neither of these reports firmly establishes the presence or absence of a common chain. Elzinga¹⁵ devised starch gel electrophoresis conditions which clearly showed that there were no similarities in mobility of haemoglobin chains of R. catesbeiana tadpole and frog. In contrast to the work of Elzinga¹⁰ and other recent reports (ref. 11 and personal communication from A. Riggs and S. Aggarwal), Hamada and Shukuya¹² have published a study of R. catesbeiana indicating an a chain, with no half cystine, common to both tadpole and frog haemoglobins.

We have confirmed the report⁴ that whole R. catesbeiana haemolysates contain between eight and ten sulphydryl groups in a haemoglobin molecule, whereas tadpole haemoglobin has none. (In an extension of earlier work in this laboratory on amphibian haemoglobins, we have re-examined the half cystine content of R. catesbeiana frog haemoglobins. Oxidation of protein by performic acid to convert cysteine and cystine to cysteic acid and extrapolation of values from amino-acid analysis after sealed tube acid hydrolysis of globin from frog haemolysates have consistently indicated between eight and ten half cystine residues in a mole of haemoglobin.) Similar studies on the four major haemoglobins purified from frog haemolysates by preparative scale disk electrophoresis13 indicate no significant differences in half cystine content. Thus Hamada and Shukuya's12 study of amino-acid composition indicating four half cystines in a mole of frog haemoglobin are not consistent with these data. The relative amount of mercury-203 bound to tadpole, frog and human haemoglobins has been estimated by counting the protein precipitated by trichloroacetic acid from whole haemolysates treated with chlormerodrin-203. Similar quantitative studies were made after separation of the haemoglobins into chains on acid-urea-starch gels. These two methods gave results which were consistent with each other and in good agreement with the half cystine content of these haemoglobins established by amino-acid analyses.

Fig. 2 shows the results obtained by applying the method of sulphydryl group detection to the four haemo-globins of frog and five haemoglobins of tadpole (R. catesbeiana) after separation and partial purification by acrylamide disk electrophoresis. The acrylamide gel containing the tadpole haemoglobin with highest mobility (No. 1 in Fig. 2) was shown by starch gel electrophoresis at low pH to contain also a minor slow moving component which did bind some mercury-203. Because the amount of this protein relative to other proteins is so small and the fact that purified tadpole haemoglobins never contain more than a trace amount of half-cystine, we believe that it is unlikely that this minor component containing reactive sulphydryl is a haemoglobin chain. Fig. 2Bshows that all major frog haemoglobin chains bound mercury-203, as did the two slow moving protein bands seen in frog haemoglobin No. 4. These bands are thought to be partially dimerized frog haemoglobin chains (see ref. 15 for discussion of frog haemoglobin dimerization), although the possibility that they are non-haemoglobin proteins similar to those of the tadpole has not been excluded. It is apparent from Fig. 2B that all frog haemoglobin chains did not bind equal amounts of mercury-203

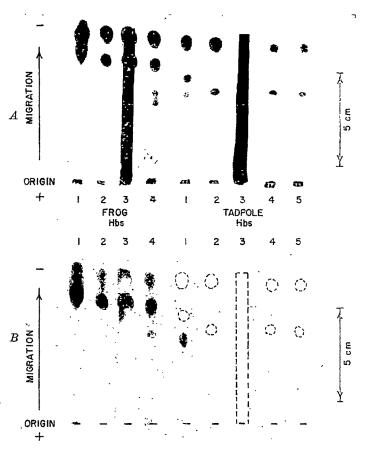

Fig. 2. A. Starch gel electrophoresis. pH 2·3, with formate: hydrochloric acid buffer, 6 molar urea, amido schwarz stain, of tadpole and frog haemoglobins (Hbs) which had been separated and partially purified from their respective haemolysates by disk electrophoresis on polyacrylamide. Samples are numbered in order of decreasing mobility on acrylamide. Tadpole Hb 1 contained a contaminant with lower mobility than either of the major chains from this Hb. To reduce the possibility that a chain with no sulphydryl groups was "buried" under a chain containing sulphydryl, strips of gel containing Hb No. 3 from both tadpole and frog were removed and re-electrophoresed in a second gel to increase the resolution and check for heterogeneity. Slightly better separation of the chains was obtained, but no additional chains were found. B. Autoradiographic detection (X-ray film) of mercury-203 bound to samples shown in A. Broken lines indicate areas containing protein but no radioactivity. Binding by slow moving non-haemoglobin band in tadpole sample 1 is evident, but no major Hb chain of tadpole bound mercury-203. All major chains of frog showed binding, although the faster chains seem to have bound less than the slower chains.

and thus did not have equal numbers of reactive sulphydryl groups*. Although free glutathione cannot account for these observations, the possibility of bound glutathione has not been rigorously excluded.

These results indicate that reactive sulphydryl groups of frog haemoglobin are found on all chains detectable in these conditions of electrophoresis and therefore that none of these chains is the same as any of those found in the tadpole. In agreement with Elzinga¹⁰ and others^{11,12}, these data indicate that a complete switch in the peptide chain content of tadpole and frog haemoglobins occurs at the time of metamorphosis.

*The relative distribution of sulphydryl between frog chains can be estimated by comparison of the relative intensities of protein stain and autoradiographic exposure. In an additional experiment, protein bands were cut from the gel and counted in a well-type scintillation counter. The ratio of counts indicated a relative reactive sulphydryl ratio of 1:3 for the faster compared with the slower chain.

Autoradiographic Study of the Effects of Cortisol on DNA Synthesis in Lymphatic Tissue

THE inter-relationships between adrenal corticosteroids and lymphatic tissue have often been described. involution of lymphatic tissue produced by adrenal corticosteroids can be related to different aspects of the growth of lymphatic tissue and to the metabolism of lymphocytes. The effects on growth of lymphatic tissue are a combination of lymphocytokaryorrhexis and the inhibition of mitosis¹. Metabolic effects include inhibition of DNA synthesis^{2,3}, RNA synthesis^{3,4}, protein synthesis3,5-7 and glucose utilization7-8, as well as producing changes in certain enzymes10.

Studies performed in our laboratories2 have demonstrated that cortisol significantly decreased DNA synthesis measured as incorporation of ¹⁴C-2-thymidine in mouse thymi and lymph nodes within 2.5 h after hormone

The results of these experiments were treatment. expressed as d.p.m./mg of DNA. There were no decreases in the total amounts of DNA and RNA in these organs when measured by colorimetric methods2. This communication reports the results of an experiment designed to determine if this decrease in DNA synthesis was a result of a direct inhibition of the biosynthetic pathway for DNA or the result of a purely destructive or inhibitory effect of cortisol on certain lymphocytes.

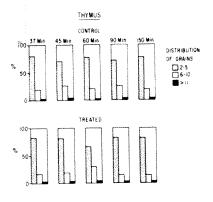

Autoradiography was undertaken in an attempt to investigate this problem. The results of this autoradiographic study should make it possible to distinguish between a purely destructive or general inhibitory effect and an actual biochemical inhibition of DNA synthesis following cortisol treatment. If cortisol acted by destroying or inhibiting cells, then the total number of cells labelled after treatment with cortisol would decrease and there would be no change in the number of grains in the labelled cells. If cortisol interferes with a particular aspect of cellular metabolism and thus produces an inhibition of DNA synthesis, the converse situation would be expected to occur, that is, no decrease in the number of labelled cells but a decrease in the number of grains in each labelled cell.

Thirty normal male mice of the CBA strain, ranging from 10 to 14 weeks of age, were used as experimental animals. The body weights varied from 17 to 25 g. All animals were adrenalectomized 24 h before injection with cortisol acetate or steroid carrier solution. mice were randomized, and divided into ten groups of three. The mice were examined 37, 45, 60, 90 and 150 min after injection of cortisol, a control and a treated group in each case.

A stock solution containing 1 mg of cortisol acetate, given by Dr Elmer Alpert, in 0.25 ml. of a suspension of 0.08 per cent carboxymethylcellulose and saline was prepared. A similar carrier solution was injected into control animals. All injections were made intraperitoneally.

At 7, 15, 30, 60 and 120 min after injection with cortisol acetate or carrier solution the animals received an injection of 1 µc. of 3H-1,2-thymidine (specific activity 14.5 c./mmole)/g of body weight in sterile saline. The animals were killed after 30 min. Thymi, spleens and lymph nodes (two axillary and two inguinal) were removed and fixed in acetic acid-alcohol (1:3) for 1 h and then in formol-saline for 24 h. Tissues were embedded in paraffin and cut 2µ thick. Autoradiographs were prepared by dipping the slides in Kodak NTB-2 liquid emulsion, and were exposed for 30 days. The slides were developed and stained with haematoxylin and eosin. The autoradiographs were examined microscopically and the results obtained were based on a count of 10,000 cells for each time period, 5,000 cells in each of the control and hormone The areas which were counted were treated groups. selected at random, and included both cortical and medullary portions of the organs. The counts were made on at least three different sections for each time period, control, or treated. Cells with two or more grains were considered to be labelled. The data were analysed statistically, using an analysis of variance.

The data in Table 1 show the percentage of labelled cells (labelling index) in the spleens, thymi and lymph nodes, in control and treated groups, at the five times after treatment with cortisol. No statistically significant differences in labelled cells between the control and treated spleens can be seen at any of the time periods studied. The 37 min values obtained from spleens of both control and treated animals are significantly larger than the rest of the measurements made on spleens at the other time intervals. There is a significant difference in labelled cells between lymph nodes of the control and treated animals 150 min after treatment. Treatment with cortisol significantly decreased the total percentage of labelled cells in the thymi 45, 90 and 150 min after treatment.

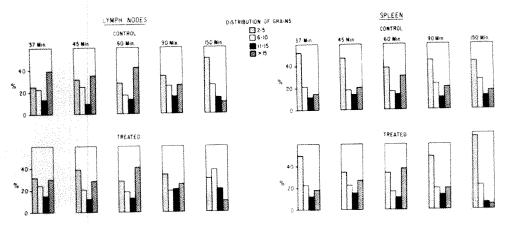

Fig. 1. Distribution of grains in the labelled cells.

The distribution of grains in the labelled cells of all three tissues is shown in Fig. 1. Distribution is broken down into groups of cells containing two to five, six to ten, eleven to fifteen, and more than fifteen grains in each labelled cell. In the case of the thymi, the last two groups are included together, because there were so few cells containing more than ten grains. No differences in distribution of grains were seen in the three organs studied at any of the times. It is specially important that in the thymi and lymph nodes, no significant differences in grain distribution were found between control and treated animals despite significant differences in the labelling The labelled cells of the control and treated indices. animals were morphologically similar, and were the larger, more immature lymphocytes.

The lack of effect of cortisol on spleens in this work may be a consequence of the large amount of myelopoietic tissue in the spleens of mice which has been reported previously¹¹. There were no differences in the distribution of grains between control and treated thymi and lymph nodes at any of the time periods which we studied. The lack of significant differences in the distribution of grain counts, when there were differences in labelling index, indicated that cortisol inhibits DNA synthesis in lympho-

cytes, in an all or none manner. Lymphocytes not affected by the hormone incorporated tritiated thymidine at the same rate as those of the control animals.

In biochemical studies², the cells which were inhibited or destroyed by cortisol were still present in the tissue when chemical extractions were performed. The number of cells able to incorporate thymidine into DNA in animals treated with cortisol would therefore be less than in controls and thus DNA synthesis seems to have been decreased. If the specific activity (d.p.m./mg of DNA) of the DNA could be measured in a cell not affected by cortisol it should be the same as that in control cells. The d.p.m./mg of DNA, however, would be altered by the presence of DNA from the dead or inhibited cells when measured chemically. The results of the autoradiographic study support this conclusion.

As we have noted, a significant difference first appeared between control and treated thymi at 45 min after treatment with cortisol. This initial decrease in labelled cells in treated animals does not appear until 150 min after treatment in lymph nodes. Rieke, Caffrey and Everett¹² believe that the lymph nodes are composed primarily of a population of long lived lymphocytes which may circulate for as long as 60 days, whereas thymi are composed primarily of a population of short lived lymphocytes which circulate for about 5 to 6 days. If this is so, an equal number of thymocytes can be expected to turn over ten times for each generation of lymphocytes in lymph nodes, and therefore the effects of cortisol would be detectable earlier in the thymus than in the lymph nodes.

The maximal concentration of cortisol in all three lymphatic tissues has been shown to occur at 7-15 min after intravenous injection¹³. It seems then that cortisol must, when it reaches its target cell, initiate a series of events which are responsible for the ultimate death of the cell. The results of this study indicate that the inhibition of

DNA synthesis after treatment with cortisol is not the result of a direct interference with a biosynthetic pathway, but is simply a result of the reduction in the number of cells able to incorporate thymidine. Other effects of cortisol on lymphatic tissue, such as decreased glucose utilization and decreased protein synthesis, also may be the result of this phenomenon.

BIOLOGY

Nucleoside Synthesis under Potentially Prebiotic Conditions

Ir is widely believed that the "prebiotic" formation of polynucleotides was a key step in the evolution of life. One of the least understood steps in this synthesis is the formation of nucleosides. Sugars, purines and pyrimidines can be made in relatively high yields from simple materials, and nucleosides can be converted to nucleotides under reasonably plausible "prebiotic" conditions, but the yield of nucleosides reported in most prebiotic syntheses is poor. We have therefore investigated certain aspects of prebiotic nucleoside synthesis.

We found that well defined adducts of deoxyribose or ribose with adenine, cytosine or guanine are formed when the dry bases and sugar are heated together at temperatures in the range 130°-170° C for a few minutes. Three compounds were obtained from adenine and deoxyribose, one of which, obtained in good yield, had an ultraviolet spectrum almost identical with that of deoxyadenosine and behaved identically on chromatography in aqueous ammonia (pH 10) and other solvent systems. It is not deoxyadenosine, however, because it hydrolyses much too rapidly in alkaline solution. Whereas deoxyadenosine withstands heating to 100° C at pH 13 for an hour with very little hydrolysis, the thermal adducts are all hydrolysed almost completely within 15 min. Carbon² has reported two diastereoisomeric compounds formed from deoxyribose and adenine in hot aqueous solution and tentatively identified them as 2,3-dideoxy-(9-purinyl)-pentoses. Two of our products are very similar to these in spectra and stability and may be the same.

In view of these findings, our two laboratories have separately investigated the photochemical reaction between adenine and deoxyribose in the presence of cyanide. We confirm the original finding that material with the same R_F as deoxyadenosine is formed³. This important product is not deoxyadenosine, however, because it is

much less stable to 0.1 molar alkali than is the natural

Thus adenosine cannot be present among the photoproducts in greater than 0.4 per cent yield and further investigation will show whether the indications that deoxyadenosine is indeed formed in small amounts are correct.

Gastrulation in Papilio polytes L.

Gastrulation has often been observed and described in the Lepidoptera, but it remains a controversial topic. Differences of opinion concern chiefly two points: (a) how does gastrulation take place; and (b) does the process take place in the same way along the whole embrye or differently in different parts of the embryo?

Schwartze¹ stated that gastrulation in Lepidoptera proceeds forwards from the back. This is to a large extent the opposite to what I have observed in our studies of Papilio polytes (Papilionidae, Lepidoptera) and is the exact opposite of the observations of Eastham² and Drummond³. Furthermore, Schwartze maintained that in Lepidoptera gastrulation is brought about by: (a) invagination to form a tube; (b) cell proliferation; and (c) overgrowth; and that these different processes can occur in different regions of the same embryo. Toyoma4 and Schwangart5 confirmed this suggestion.

According to Eastham² gastrulation takes place in the same way throughout the length of the embryo, and the germ band undergoes the following sequence of changes. (a) Proliferation of cells along the middle line followed by differentiation of this region as the middle plate; (b) an invagination of the middle plate; and (c) overgrowth of the middle plate by the lateral plates.

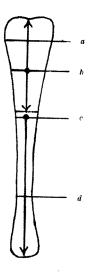

Fig. 1. Diagrammatic representation of the scheme of gastrulation. The process commences independently at level b anteriorly and at level c posteriorly and then continues in the directions indicated by arrows.

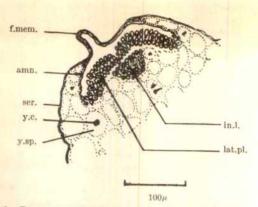

Fig. 2. Transverse section of the embryo at the completion of gastrulation through level d indicated in Fig. 1. amn, Amnion; f.mem, fold of the embryonic membranes; in.l, inner layer; lat.pl, lateral plate; ser, serosa; y.c, yolk cell; y.sp, yolk spherule.

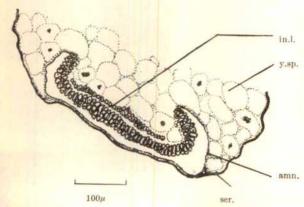

Fig. 3. Transverse section of the embryo at the completion of gastrula-tion through level a indicated in Fig. 1. Abbreviations as in Fig. 2.

Johannsen⁶ held a similar view (but he did not observe cell proliferation). Drummond's observations3 were similar to those of Eastham², who also said that Schwartze, Toyoma and Schwangart were wrong in their conclusions because "what they saw in separate regions are in fact separate processes which the germ band undergoes in sequence"7.

In view of these controversies, my observations of Papilio polytes are of interest. I found that in this insect gastrulation is initiated independently in the anterior and the posterior regions of the embryo (Fig. 1). In the anterior region, the process starts in the first part of the thorax and then extends forward to the head and backward to the posterior thoracic segments. In the abdominal region, the process starts at the anterior end and then extends posteriorly. In the head and thorax gastrulation involves cell proliferation while in the abdomen there is a medial sliding of the lateral plates to enclose the invaginating middle plate. The state of the embryonic membranes in these two regions has afforded further proof of this. The amnion and the serosa in the abdominal region show a pronounced fold at the end of gastrulation which would be expected after a considerable decrease in the width of the embryo as a result of the medial sliding of the lateral plates (Fig. 2). There is no such fold in the anterior region of the embryo for there is no movement of the lateral plates towards each other and therefore no decrease in the width of the embryo (Fig. 3).

It is also interesting to note that gastrulation by medial sliding of the lateral plates to enclose the middle plate, as distinct from the growth of the lateral plates over the middle plate, has not yet been reported in any other members of the Lepidoptera. It may further be concluded

that gastrulation shows different characteristics in various sub-groups of Lepidoptera.

Induction of Gamete Compatibility and Seed Formation in Axenic Cultures of a Diploid Self-incompatible Species of Petunia

In reviews of the control of fertilization in flowering plants, experimental methods of overcoming self-incompatibility have been discussed1,2. For example, induction of autotetraploidy by colchicine produced compatibility in a diploid self-incompatible species of Petunia3, but self-pollination of the excised whole pistils cultured in vitro did not, as one of us has shown⁴. We report here the elimination of self-incompatibility in the diploid (n=7) Petunia axillaris (Lam.) B.S.P. by fertilization in vitro, a technique devised in this laboratory5 and improved by us.

Self-incompatibility was confirmed by selfing 108 potentially fertile flowers in the field. Although germination of pollen grains was as good as that after cropollination, in 24 h the pollen tubes grew only half the distance from stigma to ovary. Also, unlike the cross-pollinated flowers, in selfed flowers the pollen tubes had not reached the ovary 48 h after pollination. Consequently, none of the selfed flowers set any fruit or seed.

To prevent chance natural pollination in our material, flower buds were emasculated and bagged 1 day before anthesis, which was easily judged by the extent of unfolding of the petals. One day after anthesis unpollinated flowers were brought into the laboratory and their sepals and petals were removed. The pistils were surface sterilized in fresh chlorine water for 10 min, washed twice in sterile distilled water and wiped with sterile filter paper. The stigma and style were removed and the ovary wall was carefully peeled with sterilized forceps, leaving behind the mass of bare ovules supported on the annular disk (present at the base of ovary) and a short length of pedicel. Thus 110 ovule masses were prepared. Of these, twenty were not pollinated, forty-two were cross-pollinated and the remaining forty-eight were heavily sprinkled with selfpollen grains collected axenically from flower buds which were ready to open (Fig. 1a). All 110 ovule masses were implanted individually in aseptic conditions in test tubes each containing 10 ml. of autoclaved nutrient medium (pH 5.8) containing in 1 1. 500 mg of Ca(NO₃)2.4H2O, 125 mg of KNO₃, 125 mg of KH₂PO₄, 125 mg of MgSO₄. 7H₂O, 0.025 mg of CuSO₄.5H₂O, 0.025 mg of Na₂MoO₄, 0.5 mg of ZnSO4.7H2O, 3 mg of MnSO4.4H2O, 0.5 mg of $\mathrm{H_3BO_3}$, 10 mg of $\mathrm{FeC_6O_5H_7.5H_2O}$, 7.5 mg of glycine, 0.25 mg of calcium pantothenate, 0.25 mg of pyridoxine hydrochloride, 1.25 mg of niacin, 0.25 mg of thiamine hydrochloride, 500 mg of casein hydrolysate, 40 g of sucrose, and 8 g of Difco 'Bacto-Agar'. The cultures were grown under diffuse daylight (10–12 ft.-candles) at $25^{\circ}\pm2^{\circ}$ C.

All twenty unpollinated cultures wilted during the first week of culture. In the forty-eight self-pollinated cultures, the pollen grains germinated in 3 h and the pollen tubes grew luxuriantly among the bare ovules and on the placentae (Fig. 1b). One day after culture, pollen tubes were also seen growing in the micropyle of ovules. In 3 days eleven out of forty-eight self-pollinated cultures turned brown and stopped growing. In each of the remaining selfed cultures between ninety and a hundred ovules enlarged sufficiently to suggest a growth stimulus caused either by fertilization or by parthenogenesis.

Embryological examination of ovules from ten self-pollinated cultures removed periodically up to 24 days after selfing demonstrated fertilization but not parthenogenesis (Fig. 1c). Five days after culture the fertilized ovules, that is, young developing seeds, were inescapably evident in the ovule mass in which the unfertilized ovules had already shrivelled and could not be seen by the unaided eye (Fig. 1d). In another 2 days the young seeds turned mealy white and resembled seeds of the same age developing after cross-pollination both in vivo and in vitro. Microtome sections of seeds formed by selfing in

vitro showed filamentous to globular proembryos and cellular endosperm (Fig. 1c). Twelve days after selfing the proembryo grew into heart shaped embryo and the characteristic testa was obvious. Mature seeds bearing dicotyledonous adult embryos were formed 24 days after selfing (Fig. 1e).

Because ten out of thirty-seven selfed cultures were killed for embryological studies, only twenty-seven were grown to seed maturity. From these a total of 1,404 mature seeds was obtained, with an average of fifty-two seeds per culture. The two highest yielding cultures gave

186 and 203 seeds, respectively.

To test germinability of seeds reared in self-pollinated cultures, seeds were sown immediately after collection—sixty on water-soaked filter paper and ten on fresh nutrient agar medium of the same composition as that on which the seeds had developed. In 15 days twenty-three seeds germinated on filter paper and seven on agar medium. Fig. 1f shows one of the seedlings formed on

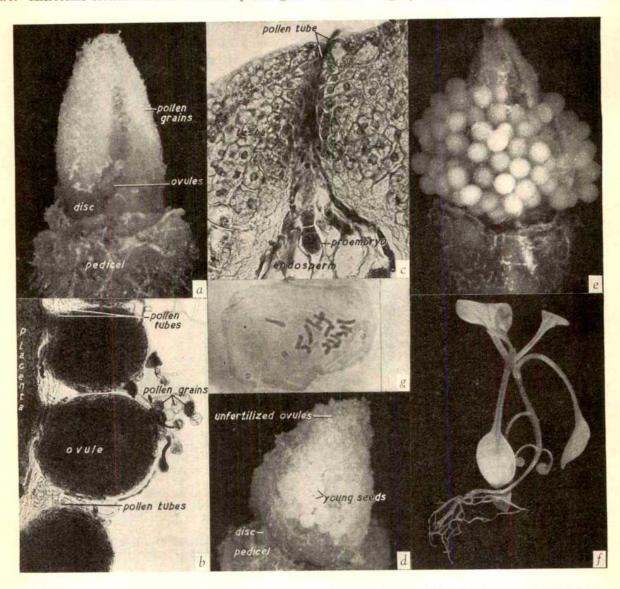

Fig. 1. Elimination of incompatibility in selfed axenic cultures of *Petunia axillaris*. For composition of medium see text. a, Whole mass of bare ovules sprinkled heavily with self-pollen grains (seen as greyish white deposit), and ready for culturing. Note outlines of a few ovules near the base and slightly upwards along middle region of the mass, the hypogynous disk and a short length of hairy pedicel (×13). b, Transverse section showing a fragment of the ovule mass 1 day after selfing. Germinated pollen grains are seen on the surface of ovules and there are meshes of pollen tubes among the ovules as well as on the placental margin (×121). c, Longitudinal section of a 7 day old seed; only the micropylar part is shown. There are pollen tube remains in the micropyle, a four celled filamentous proembryo and a few endosperm cells. The extraovular part of the pollen tube is also distinct (×306). d, Five day old culture showing enlargement of several self-fertilized ovules. Unfertilized ovules are poorly visible. Placentae and pedicel also show general enlargement, but not the disk. Compare with a (×11). c, Twenty-four day old culture showing many mature seeds, almost all with a clear testa. Barely anything is traceable in the seedless region c, Twenty-four day old culture showing many mature seeds, almost all with a clear testa. Barely anything is traceable in the seedless region the top which previously bore several unfertilized ovules (×9·5). f, Fourteen day old diploid seedling raised in culture of mature seed at the top which previously bore several unfertilized ovules (×9·5).

agar medium. Chromosomes of root tip squashes of sixteen seedlings in Feulgen reagent revealed fourteen bivalents

Of the forty-two cross-pollinated cultures, nine succumbed, fifteen were used for embryological studies and the rest were grown to seed maturity. Their embryology was similar to that of self-pollinated cultures. The total number of seeds was 991 and the average was 55.05, which is only a little more than 52, the number obtained for selfed cultures.

Gamete compatibility was effectively induced and formation of diploid seedlings accomplished in aseptic cultures of bare masses of ovules of the self-incompatible species, Petunia axillaris. This is an improvement on the work of Stout and Chandler, who could not obtain a diploid progeny of a selfed diploid parent3. Our work, now in progress, has also revealed that the technique can be successfully applied to bring about self-fertilization in part of an ovule mass, while the remainder of the ovule mass is left intact. The intact part is then available for other experiments of genetical, physiological and embryological interest.

Cytokinesis in the Green Alga Fritschiella

CYTOKINESIS in the algae, including the green algae, is generally believed to be characterized by centripetal development of the new cell wall. In the green land plants, on the other hand, a cell plate forms in the phragmoplast between two telophase nuclei and expands centrifugally until it separates the daughter cells. It is generally accepted that the land plants evolved from specialized green algae which invaded the land, and it is reasonable to assume that various cellular processes, including cytokinesis, were modified early in the evolution of the terrestrial plant cell from its ancestral green algal cell, and that these modifications were passed onto the land plants as well as to some modern green algae.

This hypothesis led to an investigation of cytokinesis in several ulotrichalean algae, including the subaerial parenchymatous Fritschiella tuberosa lyengar. Soil containing Fritschiella was sent by Dr A. K. Mitra from Allahabad, India. The alga was isolated and grown on a mineral agar supplied with micronutrients and material was prepared for study under the electron microscope using glutaraldehyde-osmium fixation and 'Epon' embedding. Fig. 1 is a section of a cell in which two telophase nuclei can be seen separated by a cell plate quite characteristic of higher land plants. Dictyosome activity can be seen in the region, and vesicles apparently similar to those of dictyosome origin seem to be fusing with the cell

IMMUNOLOGY

Disulphide Bridges of Immunoglobin GI Heavy Chains

The immunoglobulins G1 represent the major component of human immunoglobulins, with a basic four chain structure consisting of two heavy and two light chains joined by disulphide bridges1. (The nomenclature used is based on that recommended by the World Health Organization (1966).) The light chains are made up of two sections an invariable C-terminal section characteristic of each type, and a variable N-terminal section specific to each clone²⁻⁴. Peptide maps of Fd fragments^{3,6} suggest that a similar situation holds in heavy chains. In light chains the two sections are folded, each by a single disulphide bridge, to give two loops of almost equal size—the invariable C-terminal loop and the variable N-terminal loop?

The Fe region of human G immunoglobulins includes two intrachain disulphide bridges which impose on it a ring structure, again made up of an N-terminal and a C-terminal loop, resembling the ring structure of light chains. In this communication, we present evidence which suggests further similarities between disulphide bridges of light and heavy chains. We also present results concerning a peptide containing both the heavy-light and heavy-heavy interchain disulphide bridges.

The experimental approach used in these studies has been described previously⁷⁻⁹. Disulphide bridge diagonals were prepared to localize cystine peptides after digestion by pepsin, or pepsin and trypsin. Partial reduction and carboxymethylation were used in the preparation of

labelled carboxymethyl-cysteine peptides.

Disulphide bridge diagonals of a pathological (Dee) Fab fragment (made up of Fd and light chains 10) indicated the presence of four intrachain disulphide bridges in addition to the inter-heavy-light chain bridge. The two bridges usually derived from light chains could be easily identified using isolated light chains (type K, Inv b+). The remaining two intrachain bridges belonged to the Fd fragment. One of them was common to a second pathological Fab fragment (Car). The spots derived from this intrachain common bridge were also found in very good yields in normal human Fab fragments, in other isolated heavy chains of the same type and in the whole molecule. These results suggested that the fragment (Fd) of heavy chains contains, like light chains, a common and a variable disulphide bridge

The peptides from the common bridge were isolated and their partial sequence is shown in Table 1. The two cysteic acid peptides from the other bridge of Dec (not present in protein Car) could be isolated and their sequences studied. The results showed the presence of the

following disulphide bridge

It is interesting that neither of these two peptides is present in the N-terminal sequence, up to residue 84, of another myeloma heavy chain of the same type¹¹. Cleavage of the Fab fragment from protein Dee by cyanogen bromide has shown that the fragment can be split into two components. One is unretarded in 'Sephadex G-100' (6 molar urea, 0.2 molar formic acid) and contains the heavy-light bridge peptides, all the light chain intrachain disulphide bridges and the common intrachain bridge of Fd. The other fragment contained the variable disulphide bridge.

Disulphide bridge diagonals of pepsin digestion (conditions in which the danger of disulphide interchange is minimized) of intact protein Car showed the composite pattern of disulphide bridged peptides of its Fab and Fc fragments. A new set of peptides, however, could be readily identified. In particular a new peptide could be

Table 2. TRYPTIC PEPTIDES DERIVED FROM AN OXIDIZED PEPTIDE PEPTIDE OF PROTEIN CAT DIAGONALS, CONTAINING THE THREE HALF CYSTINES INVOLVED IN INTERCHAIN BINDING

The original peptide contained Lys as N-terminal, but the order of peptides 1 and 2 could not be established. Peptides 3 and 4 are ordered as in Fig. 1.

- 1 Lys-Val(Glu,Pro)Lys
- 2 Lys(Asp,Val)Lys
- 3 Ser-Cys-Asp-Lys
- 4 Thr-His-Thr-Cys-Pro-Pro-Cys-Pro-Ala-Pro-Glu-Leu

isolated which appeared to be bridged only to the light chain derivatives. This peptide contained three cysteic acid residues and after tryptic digestion gave rise to the peptides shown in Table 2. One of the derivatives was identical to the one involved in binding the light chain, while another contained two cysteic acid residues which could only be bridged with one another either as an intrachain bridge or by forming a symmetrical bridge, thus constituting the inter-heavy chain link. Models of the peptides Cys-Pro-Pro-Cys showed that it is sterically impossible to make an intrachain bridge in such a sequence to make an intrachain bridge in such a sequence to see succeeding communication) and this, added to the similarity with protein Vin (see succeeding communication) convinced us that these two cysteines were involved in inter-heavy chain bonding. Whether this bonding is parallel or anti-parallel is not known.

Partial reduction and carboxymethylation⁹ (digesting for only 4 h with trypsin) of protein Car and its Fab fragment gave rise to four and two carboxymethylated peptides, respectively, containing the bulk of the label. The results obtained are shown in Fig. 1. The studies of the resulting peptides permitted their ordering as in Fig. 2, which shows a site of papain digestion giving rise to Fc and Fab fragments. Confirmation was provided by finding Thr as the N-terminal residue of the Fc fragment from protein Car. Leu was, however, also present, suggesting that soluble papain splits the heavy chain in more than one site. Normal Fc studied in parallel also contains

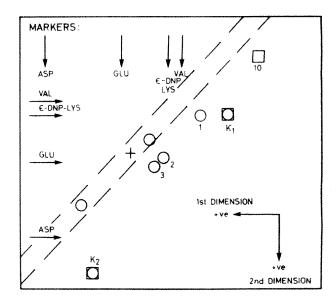

Fig. 1. Radioactive peptides obtained by partial reduction and carboxymethylation of protein Car () and of its Fab fragment (). The diagonal "map" was prepared from a tryptic-peptic digest as described previously. The digest was subjected to electrophoresis at pH 3-5, the paper was oxidized with performic acid vapour and run in a second dimension, again at pH 3-5, to complete the diagonal. The circles on the diagonal were radioactive spots containing carboxymethylated methlonine but not CMCys. The other peptides, isolated as carboxymethyl cysteine peptides, are

CONTRACTOR OF THE

Thr and Leu as N-termini, and in addition Asp and Glu, which could derive, at least in part, from light chain contamination.

The presence in a pathological YG1 protein of two inter-heavy chain disulphide bridges, both of which were reduced in mild conditions, confirms preliminary results, and is in full agreement with the results obtained independently by Steiner and Porter on another YG1 pathological protein where the full sequence around the four intra-chain half-cystines has been established12.

On the basis of studies of disulphide bridges and the general similarity of

peptides present in light and heavy chains (note, for example, that the sequence Tyr-Tyr-Cys of the variable section of all light chains is also present in heavy chains) a loop of about sixty-five residues seems to be a fundamental characteristic repeated several times in the IγG molecule. This is represented by the F'c fragment. obtained by sub-fragmentation of Fc with papain, carry ing only one intrachain disulphide bridge corresponding to the C-terminal half of the Fc fragment*. The similarity between the sequences around one of the disulphide bridges of Fd and the two bridges of Fc agrees with the hypothesis13,14 that the heavy chain originated from gene doubling of a light chain-type precursor (see Table 1).

Disulphide Bridges of a Human Immunoglobulin G Protein

HUMAN heavy chains can be classified as one of four types1,2 γ1, γ2, γ3 or γ4—which have been shown by fingerprint studies to be generally similar in their Fe regions^{3,4}. Similarities in the C-terminal regions and the disulphide bridges^{6,7} of the Fc regions of these types have also been observed. The preceding paper presents sequences around the disulphide bridges of the Fd portions of yl chains

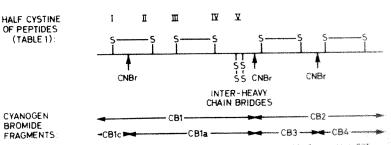

Fig. 1. Disulphide bridges and cysteine-containing cyanogen bromide fragments of the heavy chain of an IgG protein (Vin). The relative positions of cysteines I-IV are suggested by comparison with light chains (see Table 2, and Table 2 of preceding paper); the position of the inter-heavy-light chain bridge (cysteine VI) within fragment CB1a is unknown.

and gives evidence suggesting that, as in light chains*, one of the two intrachain bridges investigated is common to all IgG1 proteins, while the other is a "variable" bridge.

This communication describes the corresponding disulphide bridges of an IgG protein (Vin) of a different type-The presence of two interchain bonds between heavy chains is clearly demonstrated. Protein Vin was described as a γ2 protein in earlier papers^{7,9}. More recent results suggest. however, that it is more likely to be a 74 protein.

The heavy chain of the pathological IgG protein Vin (supplied by Dr G. P. Klein) contains, by amino acid analysis, eleven cysteine residues in a total of 450 residues. Peptides accounting for all the cysteines were isolated

from a tryptic digest of totally reduced and carboxymethylated heavy chains. tion was carried out with 2.8 mmolar dithiothreitol in 6-6 molar guanidine, 0-1 molar tris-hydrochloric acid at pH 8-2, and blocking by the addition of a three-fold excess of 14C-iodoacetic acid. Of the eleven cysteines, four comprise the disulphide bridges

of the Fe region, and one (in sequence VI of Table 1) is known to be bridged to light chains. The roles of the remaining six cysteines (peptides I-V of Table 1) were investigated by the diagonal technique19 applied to the whole unreduced molecule or its cyanogen bromide fragments. The results indicate that four are involved in intrachain bridges and two in inter-heavy chain bonding.

Cyanogen bromide cleavage of the whole molecule, followed by fractionation on 'Sephadex G-100' (in 6 molar urea, 0.2 molar formic acid11), gave rise to four fragments containing cysteine. Each of the two smallest fragments (CB3 and CB4 of Fig. 1) included two cysteine residues; those of CB3 formed the disulphide bridge nearest to the N-terminal of the Fe region, and those of CB4 formed the Fe "C-terminal loop". Sequences around these cysteine residues are presented in ref. 7. Incomplete cleavage at a methionine in a position between the two Fe bridges accounted for the presence of a third larger fragment. The fourth fragment, CB1, was the largest and accounted for all the remaining cysteine residues of the molecule.

In a chymotryptic diagonal of fragment CB1 three cystine peptides related to tryptic peptide V (Table 1) were obtained. Each cystine peptide was oxidized by per-

Daw Dee Vin Rad Vin	(11) (13) (8)	71 71 74 2	Leu-Thr-Cys-Thr-Phe-Ser-Gly-Phe Arg-He(Ser,Cys,Lys,Ala,Ser,Gly) Leu-Ser-Cys-Ala-Ala-Ser-Gly-Phe Leu-Ser-Cys-Arg-Ala-Ser-Gln-Val He-Thr-Cys-Gly-Gly-Asn	Tyr-Tyr-Cys-Thr-Gly Ala-Glu-Asp-Thr-Ala-Val-Tyr-Tyr-Cys-Ala-Arg Pro-Glu-Asp-Phe-Ala-Val-Tyr-Tyr-Cys-Gln-Gln

The peptide from Vin λ chain was isolated from a peptic diagonal of separated light chains.

formic acid and the resulting cysteic acid peptides were purified and analysed. The cysteic acid peptides obtained (V1 and V2) are shown in Table 1. Of the three original cystine peptides, one gave rise on oxidation to V1 alone, one to V2 alone and one to both V1 and V2: no other cysteic acid peptides were observed in association with any of these derivatives. The presence of a cystine peptide in which V1 is bridged to V2 (in addition to the presence of the symmetrically bridged peptides V1-V1 and V2-V2) is clear evidence of inter-heavy chain bonding in this sequence. The molecule contains no free sulphydryl groups, and so it was concluded that both cysteines are involved. Both cysteines react with iodoacetate after partial reduction, giving rise to a di-carboxymethyl cysteine peptide isolated after pepsin and trypsin digestion⁹. It is not known whether these disulphide bridges are formed in a parallel or an anti-parallel fashion. Model building suggests that both modes are possible, but that intrachain bonding between half cystines in the sequence Cys-Pro-Pro-Cys is sterically forbidden.

The remaining four cysteines (in sequences I-IV) are considered to form intrachain disulphide bridges, for they are resistant to partial reduction leading to chain separation. Two peptides related to tryptic peptides III and IV were isolated from a pepsin and trypsin diagonal of the whole molecule. They form the disulphide bridge shown in Table 1 of the preceding communication and are very similar to peptides derived from pathological IgG1 proteins and from pooled normal IgG. A disulphide bridge is most probably formed between the only remaining half-cystine peptides I and II, although this has not been directly demonstrable by the diagonal technique; however, a small fragment (CB1c of Fig. 1), including peptide I, is released on reduction and carboxymethylation of cyanogen bromide fragment CB1. Fragment CB1c probably derives from the N-terminal rather than the C-terminal section of the heavy chain portion of CB1 (see comparison of peptides in Table 2).

These results establish the presence of two intrachain and three interchain bridges in the cyanogen bromide "Fd-like" fragment of protein Vin. The similarity of peptides III and IV with the yl chain Fd "common" bridge (see Table 1 of preceding paper) may indicate that the intrachain bridge between peptides III and IV is present in all 74 proteins. A similar comparison of peptides I and II with a Yl "variable" bridge (Table 2) suggests that I and II may form a "variable" bridge; this is supported by their similarity to the "variable" cysteine peptides of light chains (Table 2). The homology in this region between Vin heavy chain and a selected z chain is greater than that between the heavy and light (\(\lambda\)-type) chains of protein Vin.

The interchain bridges are also similar to those of yl proteins in that two cystines bridge the heavy chains (ref. 12 and preceding communication) and one links the heavy and light chains,; however, it is remarkable that although the inter-heavy chain bridges appear closely similar in sequence to those of YI, the inter-heavylight chain bridges are obviously not in homologous sequences. It appears that their relative positions in the two molecules differ.

GENETICS

Sex Chromosome Abnormalities

DURING the past decade several surveys have related the incidence of sex chromosome abnormalities among the general population with that among mentally deficient patients in hospital¹⁻³. In 1963 Wegmann and Smith⁴ carried out a buccal smear survey among a male population composed of juvenile delinquents and felons. They found the incidence of positive for sex chromatin lower (1:658) than in the neonatal population (1:377) and suggested that the XXY aberration does not contribute disproportionately to juvenile delinquency or felonious behaviour. Nevertheless, evidence is beginning to suggest that genetic factors influence criminal behaviour. Jacobs et al. have called attention to the criminal behaviour of males with the XYY sex chromosome complement.

Because there are conflicting opinions about the biological effect of the extra Y and because much remains to be known about this cytogenetic aberration, we undertook a chromosome survey at a maximum security penal institution with the primary purpose of detecting XYYmales.

The institution was the Ohio Penitentiary which has approximately 3,000 male inmates. The only criterion used for the selection of one hundred men was based on height. Men 73 in. or more tall were asked to volunteer blood for the "Tall Man Project". Of the one hundred volunteers (fifty-two Caucasians and forty-eight Negroes) four were found to have a chromosome abnormality. Two individuals, both Caucasian, had forty-seven chromosomes with an XYY sex complement, while the other two, one from each race, also had forty-seven chromosomes with an XXY sex chromosome constitution.

The two with Klinefelter's syndrome were 77 in. and 74 in. tall. In addition to exhibiting the classical clinical features of the syndrome, both men were homosexuals.

The two men with XYY were 76 in. and 75.5 in. tall. Physical examination of one did not reveal any abnormalities, but the other displayed stasis ulcerations of both lower extremities. Neither was married and both denied fathering any offspring. Both men had committed numerous offences and had been in correctional institutions many times. One was thought to have an aggressive personality, while the other had not. Both were of normal intelligence. Plasma testosterone concentrations were within normal limits in each case.

The 2 per cent incidence of Klinefelter's syndrome in our preliminary survey is in keeping with that of Forssman and Hambert, who in 1963 reported a survey of the nuclear sex of 760 male patients in three Swedish institutions for criminal and "hard to manage" males of

Grey, H. M., and Kunkel, H. G., J. Exp. Med., 120, 253 (1964).

subnormal intelligence. They also found 2 per cent to be positive for chromatin. Jacobs et al.5 cite a similar study in two comparable institutions in England, where 2.2 per cent of the males were positive for chromatin. Whether criminal institutions per se have a higher incidence of Klinefelter patients compared with institutions solely for the mentally deficient is not fully known. There is some evidence that XXY cases may be slightly more prevalent in the former. Both our XXY cases were homosexuals, however, and in view of the fact that homosexuality is extremely common in penal institutions, it is interesting to speculate about a possible relationship. There is at present no information of this nature drawn from a criminal population. If significant, such information might be helpful in understanding and perhaps managing this problem.

In the thirty or more cases of the XYY syndrome that have been recorded the most outstanding clinical feature seems to be height. For some unknown reason these patients are unusually tall. Jacobs et al.5 have stated that in their original group studied a man more than 72 in. in height had an approximately 50 per cent chance of being XYY. Selecting for height, aggressive behaviour and intelligence, Welch and his group? were unable to support a hypothesis suggesting an association between these features and the XYY individual. Welch? points out that one factor in his study may be that most of his cases were Negro, and as yet the alteration has not been reported in this race. Whether there is a racial predilection in the XYY syndrome remains to be answered. In a controlled study of seven XYY patients Hope et al. s concluded that these patients do not differ markedly from controls either in intelligence or tested hostility. Furthermore, discrepancies can be noted in their concentrations of plasma testosterone. Migeon has evaluated testosterone concentrations in fourteen XYY patients and has noted that eight (including our two) have normal levels while six have a definite elevation (unpublished results). Whether the XYY syndrome indicates a familial tendency to non-disjunction has also been questioned. Further investigations are obviously necessary to elucidate the role of the extra Y chromosome in this disorder.

We thank Dr R. Brooks, W. W. Gilbert and Warden E. Maxwell for making this study possible. This work was supported in part by a grant from the US National Institutes of Health.

PATHOLOGY

Tumour Production in Glandular Stomach of Rat by N-Methyl-N'-Nitro-N-Nitrosoguanidine

WE reported1 that the subcutaneous injection of a potent mutagen², N-methyl-N'-nitro-N-nitrosoguanidine (NG), into rats induced many transplantable sarcomas at the injected loci. Schoental³ reported the occurrence of squamous cell carcinoma in the fore-stomach of rats to which NG was administered by stomach tube. Druckrey et al.4 also described the production of sarcoma in rats by the subcutaneous injection of NG. The carcinogenicity of this mutagen seemed to be well documented.

This communication deals with the production of tumorous lesions by NG in the glandular stomach of rats. with very high frequency when NG was continuously

administered dissolved in drinking water.

NG (K and K Laboratories, Inc., New York) was dissolved in water at a concentration of 33 mg or 83 Wistar strain male rats, initially 6 weeks old, were fed freely commercial CE-2 animal diet and water containing NG. Experimental rats grew at the same rate as controls. The animals were carefully autopsied when they died or they were killed after 12 months on continuous NG. In nine of thirteen rats so far autopsied, the tumorous lesions have been found in the glandular stomach, especially in the pylorus region. Four of the rats showed histologically definite serosa involvement with the rupture of muscle layer as shown in Figs. 1 and 2.

Fig. 1. Stomach of a rat killed after 12 months administration of NG solution (83 mg/l.) with a tumour at the pylorus.

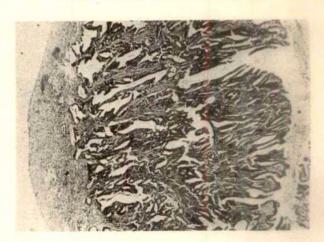

Fig. 2. Adenocarcinomatous growth with the serosa involved; same rat as in Fig. 1.

The remaining five rats have similar but early epithelial growth either at the pylorus or at the antrum. The surviving animals are being observed, in expectation of the eventual occurrence of the tumour with metastasis.

It is interesting that the fore-stomach of all the rats autopsied was quite normal. NG seems to be much more potent in producing tumour in the glandular stomach than 2,7-bis(acetamide) fluorene, 4-nitroquinoline 1-oxide, N-nitroso-N-methyl urethane or aflatoxin⁵⁻⁸.

Some of the animals showed adenocarcinoma of the duodenum, myosarcoma of the jejunum or sarcomatous lesions of mesenthelium origin. Organs other than the digestive tract were almost unaffected, except in one case which showed liver adenoma.

The mechanism by which NG causes this high incidence of tumorous lesions preferentially in glandular stomach is obscure, and is being investigated. This work was supported in part by a grant from the Ministry of Educa-

We thank Dr T. Baba for carrying out histological diagnoses.

APPLIED SCIENCE

Tensile Strength of Granular Materials

RECENTLY Carr1 and Douglas2 have commented on the equation for the tensile strength of granular materials

$$\sigma \simeq \Gamma \frac{Bt}{\bar{D}^3} \tag{1}$$

as derived by V. Smalley and myself³, where σ is the tensile strength, Γ is a numerical constant, B is the bonding force of particle to particle, t is the thickness of the fracture zone (measured parallel to the stress direction) and D is the diameter of the spherical particles which make up the ideal granular material. As originally formulated³ the constant 1' had a value of 4.6.

Carr¹ suggested a possible modification which could be introduced into Γ, which required selecting the value 8.0, from the results of Bernal and Mason4, to be the coordination number of the spheres in the random aggregate rather than using the mean value of 8.5. Bernal and Mason distinguished two types of contact in their random sphere packing, close and near. In a liquid bonded system in the pendular state, bonds should exist at both of these types of contact, so the co-ordination number which should be applied is the one for mean total contacts in a close random pack of spheres, that is, 8.5. If the dry case is being considered it might be justifiable to consider just the close contacts, in which case the co-ordination number would be 6.4. In neither case is the 8.0 value strictly applicable.

B. B. Morgan, of the British Coal Utilisation Research Association, in a private communication, however, had previously pointed out two necessary modifications in the method which do change the value of \(\Gamma \). In particular, in considering the number of bonding forces in the system it is more convenient to consider that one bond unit

exists for every two contact points on individual spheres rather than consider that every contact point represents a bond unit. This revision alone introduces a factor of two into the original formulation. The other anomaly indicated by Morgan was the unjustified appearance of the $\sin \theta$ term in equation (7) (in ref. 3) and its resulting disturbance; also a B has been omitted from equation (10) (in ref. 3). If the Morgan modifications are applied, the tensile strength equation becomes

$$\sigma \simeq 2.8 \, \frac{Bt}{D^3} \tag{2}$$

The numerical constant changes but most of the equation does not; the dependence of the tensile strength on D^3 remains. In other words, the number of bonds in the fracture zone depends on a volumetric control. For this to be valid, the model requires that the fracture section should be considered as having a finite thickness t and thus a real volume. Fracture takes place in the section in a manner somewhat similar to that described by Orrs: when an agglomerate of spheres is pulled into two pieces. the spheres must go with one or other of the two parts. If those in the fracture zone choose to remain with the part in which they are most deeply buried, the effective fracture region about these spheres can be as much as 0.5 the area of a sphere and as little as zero. The fracture scheme described by Douglas2 in which the particles come apart without themselves contributing to the strength is not applicable.

As Carr pointed out, the original equation of V. Smalley and myself is dimensionally consistent, and is also a valid representation of a specific model fracturing system in which t cannot be directly related to D. If t can be expressed in terms of D, then a dimensionally consistent expression of the form evolved by Rumpf⁶ is possible

$$\sigma \simeq 2 \frac{B}{D^2} \tag{3}$$

But there seems to be a paradox here, because to fit in with the dimensional requirement t must apparently increase with D, but in the original Rumpf formulation twas not only constant, it was actually zero in all cases. The three dimensional section of thickness, t, is more satisfactory. It still, despite Carr's objection, provides an intuitive indication that the strength of an ideal granular material is inversely proportional to the volume of the particles. If the fracture zone is three dimensional it can be thought of as a container, say a tobacco tin, the number of contacts depending on the number of spheres which can be placed in the tin and this depending on the size (volume) of the particles and thus on D^3 . In the original derivation of V. Smalley and myself, the interparticle force B was assumed to be independent of particle size and this is still a necessary condition.

Equation (6) of Douglas² is in agreement with the corresponding equations by Rumpfe and V. Smalley and myself3 in that the tensile strength was found to be directly proportional to B and this seems reasonable for real granular materials. The major problem still remains, as Morgan, showed so clearly for dry particulates, to relate D to σ for real materials.

OBITUARIES

Sir Kenneth Lee

SIR KENNETH LEE, who died recently at Ewhurst in Surrey at the age of 88, was a firm believer in the need to apply science to industrial problems, and a good friend to science. He entered the firm of Tootal Broadhurst Lee as a young man; for 54 years he was a director, and for 30 of these chairman of the firm. He had the foresight and wisdom, not only to realize how important research could be in the cotton industry, but also to pose the problems for his researchers to solve. He appointed a physicist, the late Dr R. S. Willows, as head of his research laboratory and set him to find a way to produce a cotton fabric which resisted creasing. He had faith in Willows, and gave him unquestioning support for the many years during which Willows was struggling with the problem. I was a professor at Manchester during these years, and was able to follow the progress of the quest because Willows and I often played golf together on Saturday afternoons. I remember more than one occasion when Willows used the shelter of a convenient bunker to pull out and display to me some portion of his clothing which was getting nearer to the realization of his ideal, while indignant shouts of "fore" came from a distance. He succeeded in producing a polymer inside the tube of the cotton fibre, but at first it was unpopular with the ladies because it was too springy and would not drape. This was solved, but then it would not take dyes. As is well known, the final result was the famous and popular Tootal fabrics.

Kenneth Lee, though diffident about the fact that he had no scientific education, loved meeting scientists and talking about their discoveries. But he was a shrewd judge of character, and had no patience at all with the kind of industrial researcher who makes a noise like a scientist but gets no further with a practical problem.

When I retired from the Royal Institution, the problem arose of the future of the team engaged on protein research which I had gathered there, and the happy solution was found of its migration en bloc to the Zoology Department in Oxford. There were difficulties, however, in establishing fellowships for some members of the team. Kenneth Lee was one of two friends who came to my help. His contribution was characteristically given without any question or any delay. In spite of his age and increasing frailty, he made the business arrangements to ensure that the necessary covenant would continue to run if he died.

His many public services have been recorded elsewhere; his services to science are perhaps not so well known because he was so modest about them, and they should also be remembered.

W. L. Bragg

Professor K. S. Kirby

THE death at his home on November 10 of Professor Kirby, while still at the height of his career, will be a blow for cancer research in general and the field of nucleic acid chemistry in particular.

Ken Kirby was born in Yorkshire on January 16, 1918, and, although he lived there only for short periods after leaving for the University of Manchester in 1937, his determination and great sense of humour remained those of a Yorkshireman.

He gained a first class honours degree in chemistry in 1940, but war prevented his obtaining further academic qualifications at this stage. He was directed to work at the Wellcome Laboratories for Tropical Medicine where he first worked on chemotherapy of amoebiasis. He

became interested in the structure of alkaloids and this led to five papers in the Journal of the Chemical Society (1945–1950) on the structure of quinamine, a minor alkaloid of cinchona bark. The final two papers of this series were published in collaboration with the group of Sir Robert Robinson at the Dyson Perrins Laboratory in Oxford.

At the end of the war Kirby returned to the university and obtained his Ph.D. from Leeds in 1949. His thesis was concerned with the structure of tannins and his interest in this field continued when he joined the staff of the Forestal Research Laboratory in Harpenden. The results of his extensive studies into the complex field of tannin chemistry appeared between 1948 and 1954 in a series of six papers in the Journal Society of Leather Trades' Chemists. It was during this period that Kirby gained valuable experience of the techniques of chromatographic and counter current fractionations which he later applied so successfully in other fields.

Kirby's transfer from tannin chemistry to cancer research may seem strange, but he made it because he believed that the knowledge he had of the interaction and behaviour of polyphenolic substances could be applied in the isolation and study of cellular macromolecules. He was able to convince the British Empire Cancer Campaign of the value of his ideas, and it awarded him a five-year fellowship. He joined the staff of the Chester Beatty Research Institute at the Pollards Wood Research Station on October 1, 1953, and began the work which gained him wide international recognition.

At this time, nucleic acid chemistry had received great stimulus from the publication by Watson and Crick (Nature, 171, 737; 1953) of the structure of DNA. Kirby determined to apply the discipline of chemistry to the isolation of nucleic acids in a state of purity which would satisfy an organic chemist.

The first papers describing what soon became known as "the Kirby method" for the isolation of RNA and DNA appeared in the Biochemical Journal (64, 405; 1956, and 66, 495; 1957). He was always anxious to improve and extend his methods and this led to the publication of many papers, the most recent of which, describing the isolation of DNA from mammalian tissues (Biochem. J., 104, 254; 1967) and of RNA and DNA from bacteria (Biochem. J., 104, 258; 1967), appeared only shortly before his death.

The publications reporting his methods for nucleic acid isolation are fine examples of clear and explicit experimental detail, but many biochemists found them rather complex, for they employed a number of unusual chemicals, and to the uninitiated it was not always clear why a certain procedure was used. He was often asked how he arrived at the finally published methods, to which he always replied that he was sure that anyone who had applied a logical approach to the problem must have come up with the same answer. The truth was that he had clear ideas on the nature of the bonds between nucleic acids and proteins and his methods were designed to break these bonds and so allow the purification of the nucleic acids.

Having achieved his initial objective, Kirby wished to isolate a chemically homogeneous sample of DNA or RNA and so he devised a number of counter-current distribution systems for use with nucleic acids. He subsequently employed this technique to study and attempt to separate mRNA from mammalian tissues. His paper with Kidson (Cancer Res., 25, 472; 1965) reporting changes in the counter-current distribution pattern of the mRNA of rat liver during azo-dye carcinogenesis indicated the potential of this approach.

Kirby was aware of the possibilities of nucleic acid fractionation using centrifugation in density gradients, and, typically, he was not content to rely only on sucrose gradients but sought alternatives, such as sulpholane (Biochim. Biophys. Acta, 123, 202; 1966).

Kirby was unconcerned with personal advancement and had to be persuaded to submit his D.Sc. application which was awarded by the University of Manchester in 1964. He was appointed reader in chemistry by the University of London in March 1965 and the title of professor of cell chemistry was conferred on him in February 1967.

During the last three years of his life Kirby had to fight against illness, but his output of work continued—during 1966-67 sixteen papers appeared under his name.

Peter Brookes

University News:

Reading

DR P. A. HUXLEY, at present director of research in the Coffee Research Foundation, Kenya, has been appointed head of the Department of Horticulture on the retirement of Professor O. V. S. Heath.

Announcements

THE Robert Cormack Bequest Committee has awarded a Cormack Fellowship to Mr A. S. Houston of Glasgow. The fellowship is tenable for three years and will enable Mr Houston to pursue his research at the Royal Observatory in Edinburgh.

The Winter Gordon Research Conferences will be held from January 22-February 2, 1968, in Santa Barbara, California. From January 22-26 a conference on "Electrochemistry" will take place at the Miramar Hotel, and one on the "Chemistry of Ageing" will take place at Santa Barbara Biltmore Hotel. From January 29-February 2 a conference on "Polymers" will take place at the Miramar Hotel and one on "Science, Technology and Economic Growth" will take place at Santa Barbara Biltmore Hotel. The purpose of these meetings is to stimulate research in universities, research foundations and industrial laboratories and further information can be obtained from Dr W. George Parks, Director, Gordon Research Conferences, University of Rhode Island, Kingston, Rhode Island.

Meetings

Mossbauer Effect, December 12-13, Royal Institution, London (Secretary, The Faraday Society, 6 Gray's Inn Square, London WC1).

ACOUSTICAL Holography, December 14–15, Santa Monica (Douglas Aircraft Company, Incorporated, Santa Monica, California).

AMERICAN Physical Society meeting, December 18–20, Pasadena, California (Professor W. Whaling, California Institute of Technology, 1201 East California Street, Pasadena, California).

Solid State Physics, January 3-6, 1968, University of Manchester Institute of Science and Technology (The Meetings Officer, The Institute of Physics and The Physical Society, 47 Belgrave Square, London SW1).

VALENCE and Reactivity, January 9-11, 1968, Oxford (The Scientific Affairs Officer, The Chemical Society, Burlington House, London W1).

AGRICULTURAL Sciences and the World Food Supply, March 4-6, 1968, Wageningen (The International Agricultural Center, PO Box 88, Wageningen, The Netherlands).

EXPLOITABLE Molecular Mechanisms and Neoplasia, March 6-8, 1968, University of Texas M.D. Anderson Hospital and Tumor Institute at Houston, Texas (Dr Robert B. Hurlbert, 1968 Symposium Chairman, The University of Texas M.D. Anderson Hospital and Tumor Institute at Houston, Houston, Texas).

Modern Chemistry in Industry, March 11-14, 1968, Eastbourne (The Honorary Secretary, Conference on Modern Chemistry in Industry, 14 Belgrave Square, London SW1).

RECENT Developments in Refrigeration Techniques and Equipment and their Range of Applications in the Process Industries, March 20-21, 1968, Grimsby (Mr P. Davies, Head of Group Department, The Institution of Mechanical Engineers, 1 Birdcage Walk, London SW1).

STRUCTURE Analysis: Thermal Vibrations, Disorder and Phase Transitions, April 17–19, 1968, University of York (The Meetings Officer, The Institute of Physics and The Physical Society, 47 Belgrave Square, London SW1).

STEAM Generating and other Heavy Water Reactors, May 14-16, 1968, Institution of Civil Engineers, London (The Secretary, British Nuclear Energy Society, 1-7 Great George Street, London SW1).

COMMUNICATION Satellite Earth Stations, May 20-31, 1968, London and Post Office Earth Station at Goonhilly (Mr R. E. G. Back, UK Seminar on Communication Satellite Earth Station Planning and Operation, PO Engineering Department, WS2, 207 Old Street, London EC1).

ERRATUM. In the article "Linked Groups of Residues in Immunoglobulin × Chains" by C. Milstein (Nature, 216, 330; 1967) the following variants should be moved: Roy...Threonine from position 63 to 65; Ag...Phenylalanine from 65–67; and Rad...Glutamine from 64–66.

ERRATUM. In the article "Ice Nucleation and the Substrate-ice Interface" by Duwayne M. Anderson (Nature, 216, 563; 1967), reference 7 should refer to S. Taber and references 15 and 16 should be interchanged throughout. In line 13 of the third paragraph of page 566 absorbant should read adsorbate.

ERRATUM. In the communication "Solvated Electron Spectrum in Irradiated Ice" by K. Eiben and I. A. Taub (Nature, 216, 782; 1967), reference 2 is mentioned three times in lines 4 and 5. These should be references to work of Taub and Eiben which is being prepared for publication, and not to the reference 2 which appears in the footnotes.

Erratum. In the communication "Variability of Centaurus XR-2" by R. J. Francey et al. (Nature, 216, 773; 1967), it should be the Lawrence Radiation Laboratory, and not the Levermore Research Laboratory, which is mentioned in the second paragraph. In line 10 of page 774 "type II supernovae" should read "novae or supernovae".

CORRIGENDUM. In the communication "Relationships among Functional Properties in Californian Grasslands" (Nature, 216, 168; 1967), the regression coefficient for the regression of turnover time on productivity (Fig. 3) should read r=-0.531~(P>0.1). The conclusion concerning diversity function must therefore await further data. The other two conclusions are unaffected by this error.

CORRIGENDUM. The Gairdner Foundation has asked us to make the following amendments to its list of awards (Nature, 215, 1528; 1967): Dr D. H. Copp and Dr I. MacIntyre share equally a \$5,000 annual award, Dr Copp for introducing the "calcitonin concept" of endocrine control of hypercalcaemia, and for his discovery that high calcium perfusion of the thyroid-parathyroid complex caused release of a previously unrecognized calcium regulating hormone which he named "calcitonin"; and Dr MacIntyre for confirming Dr Copp's original observations and for demonstrating that calcitonin was produced by specific cells (parafollicular cells) in the mammalian thyroid.

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, December 4

Institution of Electrical Engineers, (joint meeting with the Institution of Heating and Ventilating Engineers, at the Institution of Electrical Engineers, Savoy Place, London, WC2), at 5.30 p.m.—Discussion Meeting on "The Commissioning of Engineering Services in Large Buildings", opened by Mr P. A. Flanigan and Mr W. C. Jeffreys.

SOCIETY OF ENGINEERS (at Burlington House, Piccadilly, London, W1). at 6 p.m.—Mr Brian J. Bell: "Reinforced Plastics".

SOCIETY OF CHEMICAL INDUSTRY, LONDON SECTION (at 14 Belgrave Square, London, SW1), at 6.30 p.m.—Professor C. F. Cullis: "Recent Developments in the Controlled Oxidation of Hydrocarbons".

Tuesday, December 5

UNIVERSITY OF LONDON (at King's College, Strand, London, WC2), at 4 p.m.—Professor P. A. Bertocci (Boston): "The Cosmological Argument, Revisited and Revised".*

SOCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP—PHYSICOCHEMICAL AND BIOPHYSICAL PANEL (at 14 Beigrave Square, London, SW1), at 5 p.m.—Mr J. B. Andrews: "The Nature of Rain"; Dr J. L. Monteith: "The Nature of Dew".

University of Aston in Birmingham (at Gosta Green, Birmingham, 4), at 5.30 p.m.—Professor S. L. Cook: "Science and Decision Making" (Inaugural Lecture).

UNIVERSITY OF LONDON (at Imperial College of Science and Technology, London, SW7), at 5.30 p.m.—Professor J. G. Ramsay: "A Geologist's Approach to Rock Deformation" (Inaugural Lecture).*

UNIVERSITY OF LONDON (at the Institute of Child Health, Guilford Street, London, WC1), at 5.30 p.m.—Dr E. T. O. Slater: "The Genetics of Schizophrenia". (Last of fifteen lectures on "The Scientific Basis of Medicine" organized by the British Postgraduate Medical Federation.)*

INSTITUTION OF ELECTRONIC AND RADIO ENGINEERS (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, WC1), at 6 p.m.—Annual General Meeting, followed by the Presidential Address of Major General Sir Leonard Atkinson, KBE.

INSTITUTION OF MECHANICAL ENGINEERS, MANIPULATIVE AND MECHANICAL, HANDLING MACHINERY GROUP (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p.m.—Discussion Meeting on "Machinery for Oil Well Drilling".

Tuesday, December 5-Thursday, December 7

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2)—Conference on "Electrical Methods of Machining and Forming".

Wednesday, December 6

COLOUR GROUP (Great Britsin) (in the Physics Department, Imperial College, London, SW7), at 2.30 p.m.—Mr H. J. Charle and Dr F. W. Wood: "Colour and Food Colours"; Mrs M. H. E. Griffiths: "The Effect of Processing on Food Colours"; Mr I. F. Gaunt: "The Toxicity of Food Colours".

PLASTICS INSTITUTE, POLYMER PROPERTIES DISCUSSION CIRCLE (at 11 Hobart Place, London, SW1), at 2.30 p.m.—Meeting on "Phosphornitrils for Lubricants".

Sir Thomas Middleton Memorial Trust (at the Wellcome Building, 183 Euston Road, London, NW1), at 3.15 p.m.—Dr C. R. W. Spedding: "The Agricultural Ecology of Grassland" (Twelfth Middleton Memorial Lecture).*

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and ropical Medicine, Keppel Street, London, WC1), at 5 p.m.—Professor D. V. indiey: "The Choice of Variables in Multiple Regression".

PLASTICS INSTITUTE (at the Charing Cross Hotel, London, WC2), at 5.30 p.m.—Meeting on "The Future of the Independent Plastics Converter".

INSTITUTION OF MECHANICAL ENGINEERS. HYDRAULIC PLANT AND MACHINERY GROUP—FLUID POWER TRANSMISSION SECTION (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p.m.—Discussion Meeting on "Fluid Power Pump and Transmission Testing Codes".

ROYAL SOCIETY OF ARTS (at John Adam Street, Adelphi, London, WC2). 6 p.m.—Professor G. E. Fogg, FRS: "Food, Living Space and the Future

INSTITUTE OF FUEL (at Hatfield College of Technology, Roe Green, Hatfield, Herts), at 6.30 p.m.—Mr. R. E. Waller: "Atmospheric Pollution and Medical Statistics".

SOCIETY FOR ANALYTICAL CHEMISTRY, AUTOMATIC METHODS GROUP (joint meeting with Gas Chromatography Group of the Hydrocarbon Research Group of the Institute of Petroleum, in Lecture Theatre 1, Department of Physics, Imperial College, London, SW7), at 6.30 p.m.—Meeting on "Gas Chromatography in Process Control".

Thursday, December 7

BIOMETRIC SOCIETY—BRITISH REGION (at the Wellcome Building, Euston Road, London, NW1), at 2.30 p.m.—Annual General Meeting, followed by an Ordinary Meeting on "Statistical Methods in Archaeology". Dr F. R. Hodson: "Searching for Structure Within Multivariate Archaeological Data"; Mr James Doran: "Computers in Archaeology"; Dr C. B. M. McBurney: "Time Measurements and some Objectives of the Quantitative Approach." McBurney: Approach".

ROYAL INSTITUTION (at 21 Albemarle Street, London, W1), at 2.30 p.m.— Professor B. J. Harrison: "Biological Communication" (Civil Service Lec-

ROYAL SOCIETY (at 6 Carlton House Terrace, London, SW1), at 4.30 p.m.—Professor J. F. Enders, For.Mem.RS.: "Virus and Cancer: Problems of Relationship of Virus to the Transformed Cell and to Cancerogenesis as Illustrated by Experiments with the Oncogenic Agent Simian Virus 40" (Pariow Lecture)

University Of London (at Bedford College, Regent's Park, London NW1), at 5.15 p.m. Professor D. F. Cheesman: "Why are Lobsters Blue" (Inaugural Lecture.)*

100

Institution of Electrical Engineers (at Savoy Place, London, WC2) 5.30 p.m.—Mr R. Cafruthers: "Technological Aspects of Fusion Power at 5.30 p.m.—Mr R. Carruthers: Generation".

COLOUR GROUP (GREAT BRITAIN), CALCULATIONS GROUP AND ENTIRON-MENTAL GROUP (in the Department of Electrical Engineering, Imperial College, London, SW7), at 6 p.m.—Meeting on "Concepts of Apparent Brightness—Designing for What We See",

INSTITUTE OF REFRIGERATION (at the National College for Heating, Ventilating, Refrigeration and Fan Engineering, Southwark Bridge Road, London, SE1), at 6 p.m.—Mr I. M. D. Potter: "Design of Multi-Storey Cold Stores".

Institution of Mechanical Engineers, Process Engineering Geour (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p.m.—Discussion Meeting on "Dynamic Sealing of Rotating and Reciprocating Shafts".

Society for Analytical Chemistry, Biological Methods Group (at "The Feathers", Tudor Street, London, EC4), at 6 p.m.—Twenty-third Annual General Meeting, followed by an Informal Discussion on "Automation in Microbiological Assays", opened by Mr J. W. Lightbown.

Institution of Electrical Engineers, London Graduate and Student Section (at Kingston College of Technology, Penrhyn Road, Kingston-upon-Thames), at 6.30 p.m.—Mr R. E. Gleadow: "Electric Cars".

OIL AND COLOUR CHEMISTS' ASSOCIATION, LONDON SECTION (at Bast Ham Technical College, High Street South, London, E6), at 6.30 p.m.—Mr A. G. North: "Room Temperature Curing Acrylic Systems".

Society for Analytical Chemistry, Atomic-Absorption Spectroscory Group (at the Pharmaceutical Society of Great Britain, 17 Biognosbury Square, London, WC1), at 6.30 p.m.—Third Annual General Meeting followed by Dr. J. Stupar: "The Use of Ultrasonic Nebulisers in Atomic Absorption Spectroscopy

Friday, December 8

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 10 a.m.—Colloquium on "Automatic Testing of Electronic Devices, Components and Circuits".

ASSOCIATION OF APPLIED BIOLOGISTS (at the Royal Society of Arts, John Adam Street, Adelphi, London, WC2), at 10.50 a.m.—General Meeting followed by Scientific Papers.

ROYAL INSTITUTION, PHOTOCHEMISTRY DISCUSSION GROUP (at 21 Albertale Street, London, W1), at 1 p.m.—Miss Angela Kelly: "Exciton marle Stree Processes".

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the L.E.B., R.Ac.S. London Joint Group, at the Institution of Electrical Engineers, Savoy Place, London, WC2), at 5.30 p.m.—Mr R. F. Sims and Mr. R. L. A. McKenzie: "Aircraft A.C. Electrical Systems Using Change-over Contactors and Rapid Fault Clearance".

SOCIETY FOR ANALYTICAL CHEMISTRY, MICROCHEMICAL METHODS GROUP (in the Department of Mechanical Engineering, Imperial College, London, SW7), at 6.45 p.m.—Twenty-fourth Annual General Meeting, followed by a Discussion Meeting on "Oxygen Flask Techniques" introduced by Dr. B.

ROYAL INSTITUTION (at 21 Albemarle Street, London, W1), at 9 p.m.—Professor S. A. Tobias: "Design and Development of High-Energy Rate-Forming Machines".

Monday, December 11

INSTITUTION OF MECHANICAL ENGINEERS, HYDRAULIC PLANT AND MACHINERY GROUP—FLUID MACHINERY SECTION (at 1 Birdeage Walk, Westminster, London, SW1), at 6 p.m.—Discussion Meeting on "Giandless Pumps".

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Savoy Place, London, WC2), at 6.30 p.m.—Sir Stanley Brown: Presidential Address.

Monday, December 11-Saturday, December 16

University of Cambridge, School of Clinical Research and Post-graduate Medical Teaching (at Churchill College, Cambridge)—Intro-ductory Course on "The Biology of Skin".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

SENIOR TECHNICIAN IN THE DEPARTMENT OF GEOLOGY AND GEOGRAPHY—The Registrar, Kingston College of Technology, Penrhyn Road, Kingston upon Thames, Surrey (December 6).

LECTURER and an ASSISTANT LECTURER (suitably qualified candidates with a special interest in pharmaceutical microbiology) in the DEPARTMENT OF PHARMACEUTICS—The Clerk to the Council, The School of Pharmacy (University of London), 29/39 Brunswick Square, London, WC1 (December 8).

LECTURER or ASSISTANT LECTURER IN STATISTICS—The Secretary, The Queen's University, Belfast, Northern Ireland (December 9).

LECTURER or ASSISTANT LECTURER (medically qualified) in the DEPARTMENT OF BACTERIOLOGY AND VIROLOGY—The Registrar, University of Manchester, Manchester, 13 (December 9).

SENIOR OF PRINCIPAL BIOCHEMIST (with experience in protein biochemistry relating to immunology, and preferably with a Ph.D.) to be in charge of a new laboratory in the DEPARTMENT OF RHECMATOLOGY—The Group Secretary. The Robert Jones and Agnes Hunt Orthopaedic Hospital, Oswestry, Shreyshire (December 16).

The Robert Jones and Agnes Hunt Orthopzedic Hospital, Oswestry, Shire (December 16).

LECTURERS/ASSISTANT LECTURERS (with at least a good honours degree or equivalent plus suitable teaching and research experience) in Chemistry at the University of Malaya—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Kuala Lumpur and London, December 17).

Lecturer of Assistant Lecturer (qualified in applied mathematics) in the Department of Mathematics—The Secretary, The University, Dundee, Scotland (December 23).

Assistant Experimental Officer (with some experience of chemical and/or biochemical analysis, HNC, AIMLT in biochemistry or an equivalent qualification) in a new analytical laboratory located within the Department of Biochemistry—The Secretary, Institute for Research on Animal Diseases, A.R.C., Compton, Berkshire (December 31).

Senior Lecturer, a Lecturer or an Assistant Lecturer in Geography at the University of Zambia—The Inter-University Council, 33 Bedford Place, London, WC1 (December 31).

Research Fellow (with a Ph.D. or equivalent research experience) in the Department of Medical Chemistry, The John Curtin School of Medical Research, Institute of Advanced Studies, Australian National University, to work on the synthesis and reactions of nitrogen heterocycles—The Association of Commonwealth Universities (Branch Office), Mariborough House, Pall Mall, London, SW1 (Australia and London, January 1).

Lecturer in Medical Microbiology at Makerere University College, University of East Africa, Uganda—The Inter-University Council, 33 Bedford Place, London, WC1 (January 4).

Chair of Pathology at the University of Adelaide, Australia—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia, January 12).

Lecturer in Physical Chemistry at Victoria University of Wellington, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (New Zealand and London, January 15).

Lecturer (preferably with interests in teaching and research in land-

Lecturer in Physical Chemistry at Victoria University of Wellington, New Zealand—The Association of Commonwealth Universities (Branch Office), Mariborough House, Pali Mall, London, SW1 (New Zealand and London, January 15).

Lecturer (preferably with interests in teaching and research in landforms) in Geography at the University of Western Australia—The Association of Commonwealth Universities (Branch Office), Mariborough House, Pall Mall, London, SW1 (Australia and London, January 20).

Curator (with a degree in zoology and preferably a research degree particularly in the fields of marine, fresh water or land mollusca) of Molluscs to take charge of the Department of Malacology, Australian Museum, Sydney, maintain the collection and undertake research work—The Recruitment Section, New South Wales Government Offices, 56 Strand, London, WC2 (January 25).

Professor of Microbiology and Head of the Department of Microbiology, John Curtin School of Medical Research, Institute of Advanced Studies, Australian National University—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (Australia and London, January 31).

Assistant Lecturer (preferably with an interest in developmental biology or radiation biology) in Cell Biology—Professor L. Wolpert, Department of Biology as Applied to Medicine, The Middlesex Hospital Medical School (University of London), Cleveland Street, London, W1.

Biochemistry Gasic Grade) to work in the Department of Chemical Instrumentation and measurement) in the Department, Middlesex Hospital Medical School, London, W1.

Physicist (with experience in clinical instrumentation and measurement) in the Department, Middlesex Hospital Medical School, London, W1.

Physicist (with experience and an interest in applying physics and mathematics to physiological and medical problems) to work on new uses of short lived isotopes from the experience and an interest in applying physics and mathematics to physiological and medical problems) to work on new uses

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one or two copies of NATURE each week is:

*12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire£14.	0.0 each
United States of America (by air freight)	şaw eacn
Canada (by air freight)	SDZ each
Fisewhere overseas by surface mail	.0.0 each

(Charge for delivery by air mail on application) *Shorter periods pro rata. (Minimum three months.)

MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered:

12 MONTHS (52 issues and 4 indexes)

Number of	G.B. &	U.S.A. Canada		Elsewhere
Copies	Eire	(by air freight)		(surface mail)
3–5 6–11 12 or more	Each £13.10.0 £12.15.0 £12.0.0	Each \$46.50 \$44.50 \$42.50	Each \$50.50 \$48.30 \$46.00	Each £13.10.0 £12.15.0 £12.0.0

Multiple subscriptions must run concurrently. Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address. (ZIP essential for U.S.A.)

Parliament and the Research Establishments

FRESH from its encounter with the nuclear power industry, the Select Committee on Science and Technology of the House of Commons will, this coming parliamentary session, be tackling the problem of the defence research establishments operated directly by the British Government. Evidently the committee has decided not to restrict itself to easy problemsnext to the problem of how best to co-ordinate the making of policy on science and technology in Britain, that of knowing how best to deploy the great resources of the defence laboratories in civilian fields is the most urgent in sight. It is also an old problem. When the present government came to power in 1964, it firmly declared its intention of directing the efforts of the research establishments into more profitable fields. At one time there was talk of how the Ministry of Aviation might as a whole become a Ministry of Technology. But as things have turned out, the defence establishments remain firmly within the control of the Ministry of Defence. Collectively, they are afflicted by the kinds of troubles which have been obvious now for several years at the Atomic Energy Research Establishment at Harwell—they have often outlived the immediate task of supporting the development of military equipment and have time and spare capacity to use in other fields. But, like the AERE, they are understandably unwilling to put themselves out of business. In the circumstances, what the select committee will have to ask itself is how the defence research establishments can be reorganized in such a way as to make their great fund of talent available for other jobs. The committee should not be surprised if it finds itself covering ground which should be familiar from its inquiry into the condition of the nuclear power industry.

The committee will also have to contend with some difficulties which were not apparent in its first inquiry. For one thing, because a great deal of defence research is secret, it may be hard for the committee to operate for the most part in public. But although there is a great deal in what the civil service will argue about the need for private hearings, this is a temptation which the committee should resist as energetically as it can. So far, its influence has been enormously enhanced by the way in which evidence provided to the committee by official witnesses has been open to criticism and challenge from outside. In a sense, the publicity attending its proceedings has gone a long way to make up for the lack of expert counsellors of its own which is the most obvious of the committee's shortcomings in the past year. In the circumstances, it would be folly for the committee to allow itself to be kept behind closed doors while still not equipped with the kind of staff which could help it to design really penetrating questions. Congressional committees in the United States seem to be entirely successful in carrying out the most delicate inquiries on military matters without succumbing to the needs of secrecy. The British committee would do well to study the methods by which the military committees of Congress function before embarking on its new adventure. In the process, it will also learn how easy it is for committees to be bamboozled by a plethora of evidence. In the month-ahead, the committee should regard the appearance of memoranda which are unexpectedly voluminous with the gravest suspicion.

There remains the problem of deciding what questions to ask. The administration of particular research establishments will no doubt occupy a great deal of the time at the committee's disposal and this is not Establishments such as the Royal unreasonable. Aircraft Establishment and the Royal Radar Establishment are big spenders on a scale entirely comparable with the AERE. Like that establishment, they have also accumulated several functions not directly related to defence as well as what seems, on the face of it, to be unused capacity. This is why it would be entirely proper to ask whether some parts of these establishments would not be better placed outside the Ministry of Defence. Why not, for example, ask whether the radio astronomy at Malvern and the space research at Farnborough should not be transferred to some other organization, administratively if not physically? The problem is to balance the advantages of the present arrangements, which allow academic research to benefit from close contact with more practical activities and which give people engaged on applied research the stimulus of knowing that more distant goals are attainable, against the fact that basic research carried out at defence establishments deprives universities of funds and opportunities from which they could profit enormously. To begin with at least, it would make sense if the committee were to think of alternative arrangements under which some parts of the defence establishments could be transferred to other agencies -the Science Research Council, for example-without losing the physical services which the establishments can provide. Not merely would this increase the interchange between universities and the establishments but in the long run it would also provide more easy access by government scientists to the outside world—industry. for example.

This, however, is only the superficial part of the problem. A more serious question is the means by which the grand strategy of defence research is or should be determined. In the past, ever since the end of the Second World War, there has been no effective means by which the demands of the defence research establishments for manpower and money could be moderated by criticism from outside. It is true that there are many circumstances in which the needs of defence must be considered to be paramount, but this principle has often too easily become a means by which the defence establishments could grow without restraint and take on jobs which are not properly their business. With the reorganization of the Ministry of Defence in the past three years, it has become easier to keep the establishments properly in check. For one thing, explicit forward planning has become fashionable. More practically, central direction has become stronger. Yet there is a great deal still to be done if there is ever to be a built-in mechanism by means of which considerations which seem imperative to the Ministry of De-

fence do not distort the pattern of research and development in other fields as well. The Central Advisory Council on Science and Technology is the obvious way of striking a proper balance, but it has been less than fully effective since it was set up a year ago, partly at . least because the Ministry of Defence has responded with less than enthusiasm to suggestions that its research should be more fully co-ordinated with that of other agencies. To be fair, this unwillingness may also be prompted by unsureness about the future development of the Central Advisory Council-what kind of a body will it turn out to be? The Select Committee on Science and Technology could help a lot by helping to define more accurately the part which the Central Advisory Council should play. It may also think it profitable to consider other schemes for coordinating defence and civil research—one possibility, for example, would be an independent research council with powers to advise on and even direct the development of defence research as if this were any other public activity.

Good Start on Natural Environment

THE second report of the Natural Environment Research Council is a sober document but also a worthy one. In the short period of its existence, the council has evidently taken the line that it must begin slowly and concentrate on the creation of institutions. This is sensible enough. The council owes its existence to the report of the Brundrett Committee in 1964 which argued that there was a serious need of some comprehensive organization which could sponsor and encourage the development of research in a variety of fields, from oceanography to nature conservation. In the circumstances, it is only prudent that the council should wish to be assured of a firm base for operations. The search for a better organization for the Institute of Geological Sciences typifies the problems which the council quite properly seeks to solve. Regional offices responsible for the continuing geological survey of the United Kingdom, among other things, have to be rehoused, and there is also a need to make long term decisions about the siting of the headquarters. The difficulty here is that the institute must necessarily have a double-headed role—half of its work is academic and it should properly become a catalyst of much that happens in universities, but the institute also has administrative responsibilities for geology, mining and hydrology. It is therefore sensible that the council seems convinced that any new buildings there may be should be closely linked with universities, at least geographically. Whether it will be able to satisfy its ambition to find a headquarters outside London is another matter.

If the past year has been moderately successful, however, there is not much in the new report to suggest which way the council's institutes will develop in the years ahead. It is one thing to have a decent wish to work closely with the universities and quite

another to be energetic enough in the pursuit of such ideals. Indeed, for all its well-wishing on this subject, the council's latest report gives the impression that some of its establishments will remain self directing and essentially autonomous organisms with only the most arbitrary links with academic institutions, however closely interested these may be. This is why the council should ask itself whether there is not a case for duplicating some of its establishments in other environments. It would, for example, do no harm if some other university than Liverpool became so well endowed with facilities for research in oceanography that it could look the National Institute of Oceanography squarely in the face. There is also a case for asking that the dominant role of the Nature Conservancy in another field of operations should be somehow softened by the building up of well endowed centres of excellence at the universities. To say this, of course, implies no more than that competition between research establishments working in strictly academic fields is usually beneficial. And, in any case, anything which the council can do to strengthen its hold in the universities will help to strike a better balance within its budget, which at present seems to involve the spending of too great a proportion of its resources on institutions and too little on grants for supporting research projects.

Russian Eclipse

THE following description of the Russian preparations for the solar eclipse of September 22, 1968, has been supplied by Evald Mustel, chairman of the Astronomy Council of the USSR Academy of Sciences, and Nataliya Yegorova, an associate of the Astronomy Council of the USSR Academy of Sciences, through the Novosti Press Agency.

On September 22, 1968, a total solar eclipse will be observed on the territory of the USSR. A full phase band will start near Severnava Zemlya, North Land, will cross the Kara Sea and enter the mainland near Vorkuta. It will then go nearly straight to the south along the 62nd to the 64th meridians. Then, turning sharply to the south-east, it will pass slightly north of Alma-Ata, west to west China and will end north of Lobnor Lake.

Although the 1968 eclipse is unfavourable for observations because of the short length of time for which it will be visible—a maximum of 42·7 seconds—and the low height of the Sun above the horizon—a maximum of 18·7°—many Soviet astronomers are going to observe it. It is proposed to place nearly all expeditions near the railway station of Kargopolye, on the Sverdlovsk–Kurgan line, where the maximum duration of the eclipse and the maximum height of the Sun above the horizon are combined with relatively favourable meteorological conditions.

In the optical range, all traditional types of eclipse observations of the corona, chromosphere and photosphere will be conducted. Associates of the astrophysical observatory of the Georgian Academy of Sciences, as well as the astronomical observatories of Kiev, Lvov and Ural Universities, intend to obtain large-scale photographs of the inner, middle and outer coronas important for studying coronal structural Kiev and Lvov Universities are planning to observe the degree of polarization of coronal emission, while the observatory at Lvov will undertake colorimetric observations of the corona. The spectrum of the corona will be photographed by the Abaetumani Astrophysical Observatory of the Georgian Academy of Sciences, and by the astronomical observatories of Kiev, Ural and Kharkov, as well as by the Sayanskaya Solar Observatory.

The observatory of Kharkov University is planning to take direct photographs of the chromosphere at the wavelength of the hydrogen a-line. The sun department of the Institute of Terrestrial Magnetism, the Sayanskaya Solar Observatory (with the Echellete spectrograph) and the main astronomical observatory of the Ukrainian Academy of Sciences are planning to study the chromospheric spectrum, which requires great skill in observations and subsequent thorough processing. The programme of the Sternberg Astronomical Institute includes taking pictures of the chromosphere and the corona with the Fabry-Perot standards which make it possible to evaluate the distribution of the temperature and the turbulence velocity around the solar disk.

In addition, the programme of the Sternberg Institute and the main observatory of the Ukrainian Academy of Sciences includes investigations of the photospheric spectrum on the solar limb, and the behaviour of spectral lines near the limb. Ural University will do similar studies using a stationary horizontal solar telescope. The Sternberg Institute will also be making photoelectric records of fluctuations from the centre of the disk to the limb in individual portions of the photospheric continuous spectrum.

Finally, the main astronomical observatory of the USSR Academy of Sciences and the observatories of Leningrad and Kiev Universities are preparing to record solar emission during the eclipse. These recordings will include investigations of the fine struc-

ture of local sources of the slowly varying component of the solar emission at 4 cm, and of the distribution of radio brightness of local sources on the Sun, and on the limb of the quiet sun. Investigations will also be made of the degree of inhomogeneity of the corona, and of the radio sizes of the solar disk in the centimetre wavelength range.

Transport Arranged

THE Minister of Transport, Mrs Barbara Castle, seems now to have completed most of her planning for the development of transport in Britain in the years ahead. The last of four white papers on transport policy was published earlier this week, and deals with the organization of public transport (Cmnd 3481, HMSO, 3s. 9d.). The outstanding proposal among those contained in the White Paper is that responsibility for public transport systems should be transferred to public transport authorities set up in the various regions of the United Kingdom. On some occasions, this will mean that municipal buses are nationalized. Because most transport undertakings are at present in public ownership, however, the principal effect of the new proposal would be to transfer to regional authorities responsibility which is at present centred on the central transport commission.

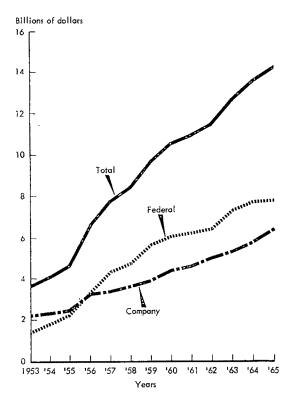

Mrs Castle hopes that her plan will commend itself to those who argue that transport systems should be planned in such a way that they are closely integrated with city planning, and she is no doubt correct in that assessment. It is also reasonable that, if the regional transport authorities are to be subsidized, the injection of money should be used to pay for capital resources rather than for running costs. Some difficulties stand out, however. For one thing, there is no assurance that within the framework of the proposals now put forward it will be possible to find room for the kinds of technical developments in transport which are necessary in modern cities. Monorails may be out of fashion, but there is always a possibility that a regional transport authority would be more anxious to guard the sanctity of its existing stock of buses than to introduce small road transport vehicles, for example.

American Industrial Research

Industry in the United States seems to be playing a decreasingly important part as a performer of research and development. It still does the lion's share—70 per cent in 1965—but this represents a decline from the peak reached in 1957, when 78 per cent of all research was done by industry. The growth in the industrial sector, 5 per cent between 1964 and 1965, is the slowest of all. These figures, published by the National Science Foundation in a report called Basic Research, Applied Research and Development in Industry (US Government Printing Office, 65 cents), show that despite the change in emphasis, industry in the United States still does a greater proportion of the work than does industry in Britain. In 1964–65, British industry was doing about 60 per cent of all research and development work.

The slower growth recorded by industry in the US seems to have been a consequence of a deceleration of federal support; industry's own contribution has continued to rise at the same rate for several years.

Between 1953 and 1959 the federal contribution to industrial research expenditure increased sharply, and overtook the industrial contribution in 1956. Since then the scales have begun to tip the other way. American industry in 1965 financed some 45 per cent of the research work which it carried out, while federal support made up the rest.

The changes in distribution are naturally overshadowed by the sheer growth of research expenditure since 1953. Total expenditures have increased since then from \$3,630 million to \$14,197 million. Companies in the aircraft and missile business accounted for more than a third of this, some \$5,120 million, while research in the electrical equipment and communication business amounted to \$3,167 million. Just under 90 per cent of the aircraft and missile research was supported by federal funds, as was more than 60 per cent of the electrical and communication research. At the other end of the spectrum, the chemical and allied products industry found 85 per cent of its research expenditure from its own pocket.

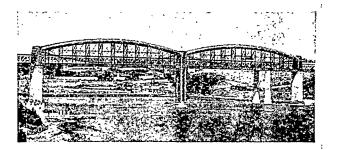

Overwhelmingly the advantage lies with the big battalions. The eight companies with the largest research and development expenditures accounted for 11 per cent of net sales, 13 per cent of total employment, and 47 per cent of all federally supported research. There were some 13,400 companies conducting research in the United States in 1965, but 87 per cent of the research was done by about 3 per cent of the companies. Among large companies, 29 had research and development programmes costing more than \$100 million and made up \$9,000 million of the total expenditure.

More than half the scientists and engineers working in industrial research worked in the aircraft, missile, electrical and communications industries. Together with chemicals and allied products, machinery, motor vehicles and other transport equipment, these industries employed 81 per cent of the qualified manpower. In January 1966, the total number of scientists and engineers employed in research and development was 358,900.

Monumental Masonry

In 1955 Mr Michael Rix invented the name industrial archaeology. Although some say that industrial monuments are too recent to be considered archaeological relics, Mr Rix points out that an eighteenth century ironworks, the model T Ford and the crystal set are really as out of date as a Stone Age axe. In a pamphlet called Industrial Archaeology, published by the Historical Association (3s. 6d.), Mr Rix makes a convincing case for industrial archaeology and, in particular, for preserving the monuments of the Industrial Revolution before it is too late. This is especially important in Britain, of course, where the Industrial Revolution began and where there are many of its relics.

The pamphlet makes encouraging reading, and the increase in the number of industrial museums, the founding of the journal Industrial Archaeology and the encouragement and indirect support of the Government point to the rapid expansion and interest in industrial archaeology. The most immediate problem is to assess the importance of sites and items. Nobody knows exactly what relies of the Industrial Revolution are still left scattered about the country. A national survey of industrial monuments is being made under the auspices of the Council for British Archaeology, which receives some support from the British Government. This survey is being co-ordinated by Mr Rex Wailes, who, before joining the Council for British Archaeology eighteen months ago, acted as a consultant to the Ministry of Public Building and Works. Mr Wailes collects information and presents proposals for the preservation of industrial monuments to the council. If they are agreed upon, the council makes representations to the Government asking for a preservation order.

Railway bridge across the Saltash, built by I. K. Brunel for the Great Western Railway. The modern suspension bridge can be seen in the background. (British Rail photograph.)

At the same time, a national record of industrial monuments is being maintained at the Centre for the Study of the History of Technology at Bath University of Technology. But progress is slow and depends almost entirely on the work of individuals and local archaeology societies. In a progress report in the

current issue of *Industrial Archaeology*, Dr A. Buchanan, the director of the centre, says he has adequate records for only three counties—Hertfordshire, Somerset and Staffordshire.

Many monuments have been preserved. The New Lanark industrial estate, which incorporates the technology of Arkwright with the social planning of Robert Owen, and Coalbrookdale, where Abraham Darby first successfully smelted iron ore with coke, are obvious and famous examples. But these are exceptional and the list of industrial monuments which have been destroyed is depressingly large and growing steadily. As things are, the relics of the transport revolution, canals, turnpike roads and railways, with their magnificent bridges, are more than ever threatened.

Oxford on Iron Rations

from our Oxford Correspondent

This week the governing bodies of British universities will be examining the details of their Quinquennial Grants from the University Grants Committee, but few of them, perhaps, with as little delight as Oxford. Yet at first sight, Oxford's grant seems generous. In 1965–66, of Oxford's total income of £8.0 million, the UGC provided £5.25 million, with a further million pounds of government money coming from research councils and other public bodies. By comparison, the recurrent grants for the next five years are:

1967-68 1968-69 1969-70 1970-71 1971-72 £6·1 m. £6·2 m. £6·4 m. £6·6 m. £6·8 m.

Equipment is to be provided for separately from these grants.

In fact, the increase in the grant since 1966 will do little more than cover increases in salaries and prices during the period so that, according to the Hebdomadal Council, there will be no additional funds available for new expenditure next year. At the same time, universities are having to repay sums to the Grants Committee in compensation for the increase in their incomes from the higher fees of overseas students. Oxford, however, refused to increase these fees, so that £63,000 will have to be paid from the university's own funds, with none of the income for which it would have been a compensation. These payments are expected to increase over the five years.

Even if the Quinquennial Grant had been less parsimonious, the devaluation of the pound would doubtless have forced economies on most university faculties, especially on the science side. Ironically, devaluation will harm those university departments the growth of which the committee had hoped to encourage by The Bodleian Library, for increased allocations. example, has long been short of funds; in 1963-64 its total income was only \$1.75 million (at the old rate) compared with nearly \$6 million for Harvard Univer-The Quinquennial Grant contains sity Library. provisions for increasing library expenditure by 20 per cent per student. How far this will be vitiated by devaluation and the increased cost of some books, it is too early to say. In the same way, the growth of Middle Eastern and Latin American studies will be slowed down and these departments, as well as the science faculties, will be waiting earnestly to hear that the government will compensate for the fall in the value of the pound.

There is therefore little hope that Oxford will be able to expand its activities, even though it receives public money from a variety of sources. Increasing college fees—paid for in the main by local authorities—is no light matter and, even if tuition fees are increased. colleges will be able only to appoint a few new tutors to help out penurious university departments. Even so, the majority of college tutors depend in part on university emoluments, paid for by the UGC. Finally, whatever elasticity of this kind there may be in arts faculties, there is far less in science, where the expense falls almost entirely on the Grants Committee and the various research councils. These latter will shortly be issuing their own estimates; if they are equally disappointing, then Oxford will indeed have to live on rather sparser fare than might have been hoped.

Money for Harvard

HARVARD UNIVERSITY is trying to raise nearly \$50 million for an ambitious (some might say, luxurious) programme to make science more exciting for undergraduates at Harvard College. Of the total sum. \$14.5 million will be used to build a new science centre, with laboratories, computers and a library, in which undergraduates will be encouraged to do research. Their efforts to do this now are inhibited by the demands of graduate and post-doctoral research. Another \$12.6 million has been budgeted for a new centre for research and teaching in biochemistry and molecular biology (fields in which Harvard has four Nobel Laureates). A project is also indicated to endow five professorships, in astronomy, biology, engineering, mathematics and physics.

More than one fourth of the several thousand undergraduates at Harvard take degrees in science. The others, who read humanities or social sciences, must spend at least a small fraction of their time at Harvard studying science or the history of science. They, as well as the science undergraduates, will benefit from "a programme for science" as it is being called. Harvard says that it is conscious of its responsibility to give all of its students, especially those who will become teachers, some acquaintance with what modern science is about.

Physics Directory

The ninth edition of the Directory of Physics and Astronomy Faculties has been published by the American Association of Physics Teachers and the American Institute of Physics for the period 1967-68 (\$3). The purpose of the directory is to list those universities in America, Mexico and Canada which offer physics courses and the members of staff who teach these courses. The information which has been collected is part of the procedure used to improve coverage of the National Register of Scientific and Technical Personnel which is maintained by the American Institute of Physics under the sponsorship of the National Science Foundation.

Also listed this year are departments of astronomy and astrophysics, but this section is incomplete and it is hoped that better coverage will be given next year. The directory is divided into seven parts: part one provides a geographical listing of personnel and institu-

tions in the United States; part two includes a geographical list of personnel and institutions in Canada; and part three provides a similar list for Mexico. Parts four, five and six are delegated to an alphabetical index of colleges and universities in the three countries, and part seven is an alphabetical index of personnel.

Progress in Time Sharing

In August 1966, the Computer Board was set up under the chairmanship of Professor B. H. Flowers to carry out, on the basis of planned development, the proposals for providing computers in British universities and research councils in the light of the Flowers Report of January 1966, and for ensuring that the facilities provided were fully used. The five Board members are Professor C. E. H. Bawn of Liverpool University, Professor Gordon Black of the National Computing Centre, Professor D. J. Black of Edinburgh University, Mr J. K. Steward of ICI, and Lord Halsbury; Mr L. S. Rutterford is secretary to the Board.

In accordance with the recommendations of the Flowers Report, which suggested the expenditure of a total of £17.68 million over a period of five years for the provision of computer hardware in universities, a regional centre is now being set up in Edinburgh. This is one of the three suggested centres—London, Manchester and Edinburgh—at which large computers with special facilities are to be installed for the general use of universities in the areas. The concept of a multiple access time sharing system at Edinburgh is, however, an additional feature which was not visualized at the time of the report. In comparison with the actual cost of the hardware, additional costs of consoles and software to furnish the multiple access systems are small and will not represent a major item of expenditure above that recommended by the Working Group. The University of Edinburgh will soon be taking delivery of a British computer, the English Electric 4/75. Several agencies have contributed to the cost of the computer and the software: these include the Computer Board, the Ministry of Technology and various research councils, particularly the Agricultural Research Council. The cost has not yet been settled, but the total so far committed is about three-quarters of a million pounds. Development of the system is being shared by the university and the manufacturers. Whether or not multi-access systems will be established at the two other centres has not yet been decided.

The University of Newcastle upon Tyne has already taken delivery of an American IBM 360/67 multi-access computing system which was installed in October and is currently undergoing tests. When operational, use of the machine will be shared by Newcastle and Durham Universities. £575,000 of the total cost of the computer was provided by a grant from the Computer Board. Communication terminals will be available in various departments of both universities and satellite computers can be attached to the central computer.

Research workers in two universities are developing their own multi-access facilities by building on to existing computers already at their disposal. Thus a smaller computer providing these facilities has been developed at Edinburgh University under Professor D. Michie for application to medical research work. This is based on the Elliott 41/20 model which was delivered

in early 1966. The software has been produced in the university, but the cost of salaries and expenses was covered partly by the MRC, partly by the SRC and partly by the university itself. There are twenty consoles connected to the system, any eight of which can be used simultaneously. In addition there are two remote consoles which are attached by telephone: one is at the National Institute for Medical Research at Mill Hill and the other is at the Department of Social Medicine at Edinburgh. The system involving the twenty consoles has been operational since this summer, but the two remote consoles will not become operational until the end of the month.

Serious work on multi-access systems at Cambridge began at the end of 1964 with the design of a multiplexor to attach to the Titan computer. Development of the hardware was a joint exercise between the university and International Computers and Tabulators, Ltd. The cost of the consoles and multiplexor was met by the SRC while the disc store, which represented the major item of expenditure, was ultimately paid for by the Computer Board. By November this year the multi-access computing service was running at more than a hundred hours a week. At present there are about twenty-five consoles and between sixty and seventy regular users: most of the consoles are in the mathematical laboratory, but there are others in the engineering laboratory, the chemical engineering and the medical psychology laboratories. Workers at Cambridge maintain that the multi-access system has greatly increased the productivity of its users, and has materially diminished the demand for specially rapid service through the ordinary computing system.

Indeed, multiple access computing systems are very much a subject of objective research and exploration in leading British universities concerned with computer science. Applications for the time sharing systems are being considered by the Computer Board, which has in mind the linking up of computer systems in various universities, particularly in the south-west—to provide a complex computer network.

Despite the advantages of a multi-access system which gives a large number of users immediate access to the large computing system and which allows intimate contact between the worker and the tool as well as providing—in principle—quick and easy programme development, several problems have to be overcome. For example, considerable difficulties have arisen at Newcastle in connexion with the software and the system is far from satisfactory. Similar difficulties have been encountered in the USA with the same model. Evidently, the most economic arrangement has yet to be worked out.

Environmental Research

THE Natural Environment Research Council enters its second year in a better state of organization than in its first. The report of the council for the year ending March 31, 1967 (HMSO, 11s.), describes what has been happening. Broadly, the council seems to have been digging itself in as a permanent part of the Civil Service, by setting up a headquarters (from which it has since moved), establishing specialist committees, and defining the details of recruitment and employment of staff. Scientifically, the council is making an attempt to originate policies of its own, and organize

more cohesively the research programmes it is responsible for. Already there are some signs that the divisions between disciplines which the council inherited have softened, although the establishment of separate committees to serve the separate arms of the council's activities is bound to preserve some of the distinctions.

The council is responsible for research in the United Kingdom which is concerned with the environment. This covers geology, oceanography, the Nature Conservancy, the Antarctic Survey, hydrology and forestry, and each of these broad areas has been provided with an advisory committee to establish policy and make recommendations about grants. The total income of the council over the year was just over £5½ million; the table shows how this income was distributed among the competing interests:

Institute of Geological Sciences	£1.34 m	25.60 per cent
Nature Conservancy	£0.96 m	18.40, ,, ,,
National Institute of Oceanography	£0.65 m	12.40 ,, ,,
University grants	£0.68 m	13.04 ,, ,,
University training awards	£0·44 m	8.33 ,, ,,
Meteorological Office	£0.08 m	1.46 ,, ,,
Hydrological Research Unit	£0.08 m	1.45 ,, ,,
Grant aided laboratories	£0.70 m	13.30 ,,
Administration	£0·17 m	3.32 ,, ,,

The main force of reorganization has so far been felt in the Institute of Geological Sciences (formerly the Geological Survey). Here a much wider research programme has been agreed, and the institute will be responsible for geological investigations of the continental shelf. The discovery of natural gas in the North Sea, and the increasing importance of the exploitation of sand and gravel, have stimulated this new development. During the summer of this year the first investigation was made, in the north Irish Sea, and preliminary work has also been done off Scotland and in the Moray Firth. There is a good chance that the institute will be moving out of London at some time in the future, although so far it has been impossible to find anywhere suitable. Difficulties of accommodation in London have proved "the most hampering factor for smooth progress during 1966" the report says, but the situation has been eased by the leasing of another building in Princes Gate, not far from the museum.

The Nature Conservancy has also undergone a complete reorganization since the coming of the council. The research has been regrouped into eight groups which the council has decided to call Habitat Teams. Each is responsible for a different habitat—Monks Wood Research Station looks after lowland grasslands and grass heaths, and wildlife in the agricultural environment, for example, while hill grasslands are the responsibility of the group at Bangor, and wetlands that of the group at Edinburgh. One of the council's principal preoccupations since the Torrey Canyon incident has been the study of coastal ecology, and this will be studied by the team at Furzebrook until the research station at Norwich is complete. One interesting conclusion reached by the Unit of Grouse and Moorland Ecology during the year was that grouse stocks can be considerably improved by burning small fires all over the grouse moors. The survey shows a direct correlation between the number of fires started and the grouse stocks, and the report suggests that by better management many of the Scottish grouse moors could be brought back to their former glory.

The most fashionable part of the council's work is The Ministry of Technology, that in oceanography. the report says, "is concerned to identify technological developments which can make use of any spare capacity of the Atomic Energy Research Establishment (Harwell) that may arise in the near future". The report then goes on to suggest that the ministry is thinking of turning Harwell's attention towards the technology of the sea and the sea-bed, and that this was the reason for the conference on the subject at Harwell in April this year. But the report makes clear that it intends to remain the prime co-ordinator of marine scientific research in Britain and to encourage the ministry to plan the commercial exploitation of the research findings. In other words, if oceanography is to be promoted to a major research industry by the British Government, the council has no intention of being outmanoeuvred by Harwell. It is clear, though, that more research vessels are going to be needed; the council recommends that a new vessel primarily intended for biological research, and for use by the Scottish Marine Biological Association and the universities, should be built. The Institute of Geological Sciences will need a new dual-purpose vessel, again to be used in conjunction with the universities, and two smaller vessels will be needed for coastal work. Finally, the council has made provision for a two-man submersible, capable of operating at 100 fathoms, with a support vessel. It would be surprising if the development of just such a craft by a British firm (see Nature, last week, 216, 845; 1967) can have been entirely coincidental.

Apart from the ecology and geology of the coastline, and the geology of the continental shelf, the other major new development described in the report is in the hydrology and biology of inland waters. This will be done, the report says, by building up the Hydrological Research Unit so that it can carry out a comprehensive programme of research into all the factors affecting water balance in catchments, and develop an effective means of co-ordinating work in hydrology being done elsewhere. As if to demonstrate that this is more than a fine phrase, the council points out that the research effort of the unit has more than doubled since the council took over responsibility for it two years ago. And the council now intends to treble the present research effort by 1970.

All this has not been done without a marked expansion of the administrative side of the council. When the report went to press the staff was some seventy-five, and since then a further expansion to almost 100 has occurred. As a result of this expansion, the council was forced to move out of its offices in State House, and has now taken over eight floors in Alhambra House in Charing Cross Road. Even this, however, seems to be barely adequate for the council's purposes.

Research for Industry

THE Ministry of Technology is to set up industrial units in British universities to help industry by providing commercial consultancy and research services. For a start, the units will be established in four universities, at the College of Aeronautics at Cranfield and at the Risley establishment of the Atomic Energy Authority. The ministry has made a launching grant of about £1 million to get the units started, on the condition that

956

each appoints a full time manager to look after the commercial activities. Once the centres are operating successfully, it is expected that they will be self supporting, and the money will be freed to start new centres at other universities.

The first centres reflect the British Government's interest in tribology—the study of interacting surfaces in relative motion, including friction, wear and bearing design. The universities of Leeds and Swansea and the establishment at Risley will be concerned with tribology. The University of Strathclyde has a general brief covering the whole of engineering; Cranfield will look after precision engineering and Bangor will be responsible for instrumentation and control engineering. Each unit will be undertaking contract research for industry and the project is intended to be a thoroughly commercial one. But the ministry foresees no conflict between the units and the universities proper, and the minister himself goes near to saying that the commercial pressures will be a good thing for all concerned. "The universities are going to sell themselves to industry," Mr Benn declares.

In approving the centre at Risley, the minister seems implicitly to have rejected the recommendation of the Select Committee on Science and Technology, which reported last week. The committee said that the authority should not undertake work on subjects not inextricably linked with its primary task. Mr Benn said that the policy of diversification is "well established".

The emphasis on tribology, and the name, derive from a working party set up by Lord Bowden when he was Minister of State at the Department of Education and Science in 1964. The committee, under the chairmanship of Mr H. Peter Jost, was the originator of the now celebrated claim that industry could save £500 million a year by the better use of lubrication. In support of these figures, Mr Jost has quoted the experience of East Germany, where training in lubrication has been made compulsory, and qualified lubrication engineers have been appointed to state owned works. Within a few years, Mr Jost said, the East German steel industry has saved £2-£3 million, which would have meant £21 million in Britain. One of the conclusions of the Jost report was that inadequate training in tribology would be a major stumbling block-but Mr Benn's new proposals make no direct provision

Glass Reinforced Plastics

A HAPPY accident in 1940, when catalysed polyester resin was spilt over several layers of glass fibre, produced the first glass reinforced plastic (GRP). Since then the highly satisfactory structural properties of this material have been studied and it can now be considered alongside the more conventional building materials of concrete and steel. The development, properties and design qualities of glass reinforced polyester resins were described by Mr Brian J. Bell at a meeting of the Society of Engineers on December 4.

Polyester resin has the great advantage of polymerizing at room temperature and low pressure. GRP can therefore be moulded (layed-up) by hand, and can be used for moulds of any size and shape. It is resistant to weather and many chemicals. These advantages are somewhat offset by the slowness of production

compared with injection moulding methods, and skill is required to produce a material of consistent strength. Glass fibre for reinforcement and the resin itself are expensive, but no costly equipment is required for production of GRP. Fillers can be added which alter the gelation time, and mechanical, thixotropic and self-extinguishing properties of GRP and the form of reinforcement can also be chosen to suit the required design properties. The most common form of reinforcement is the chopped strand mat in which 2 in. random strands are bonded together with resin to form a mat which weighs from 1 to 2 oz. per square foot.

GRP can be produced by contact pressure and by low or high pressure moulding. Each method has variations which are introduced to suit the size, shape, dimensional tolerance, cost, strength and quantity of the required product. In all cases a release agent is required for releasing the product from the mould. Mr Bell gave examples of the general properties of various laminates that can be made from GRP, and compared its properties with those of mild steel. Volume by volume GRP can be almost twice as strong as mild steel, while weight for weight it can be thirteen times stronger. But sometimes it lacks rigidity, and variations can occur in mechanical properties because of differences in manufacturing conditions or in composition. Mr Bell described ways in which the limited span of GRP can be extended, particularly by folding the material—despite the unsolved problem of prestressing, GRP obviously has a great future.

Another Food Supplement

LAST week the American University of Beirut announced that a high protein food supplement, called "l'aubina", had been developed in Beirut under the direction of the Columbia University Institute of Nutrition Sciences and financed by the United States National Institutes of Health. It is the latest addition to the growing list of food supplements developed from local products in various parts of the world in an attempt to combat local malnutrition with locally grown produce. "L'aubina" is made from chick peas and parboiled wheat-both are grown in the Middle East, North Africa, India and Pakistan—with small amounts of bone ash and skim milk. It is easy to make-apparently any food manufacturer could make it with existing machinery—and cheap. In tests, the nutritional health of children was maintained by a daily supplement of 7 ounces of "l'aubina" which would cost only about 2s. 1d. (25 cents) to produce. It contains 17.1 per cent protein-about the same amount as roast leg of lamb—adequate amounts of vitamins A and D and some vitamin B and calcium.

The question now is whether a commercial producer can be found to produce "l'aubina" in bulk and, even more important, whether it will be accepted by those who are suffering from malnutrition. Past experiences are not at all encouraging. In Peru, a supplement called "Peruvita", which is made from the local plant quinoa, was developed over a period of five years but abandoned last year because it was not accepted. Similarly in Guatemala, "Incaparina". made from cotton seed and sorghum, has not been accepted. It is still produced but only reaches 2 per cent of the children in the country. So great is the prejudice against these supplements that even

when they are offered free they are not used. Giving them away often increases suspicions. Anything which is free must be no good, is the feeling. Recent events in India suggest that some people would rather starve than change from eating one cereal to another. It may be encouraging that in experimental tests with "l'aubina", the children seemed to like it and their mothers have accepted it.

Controlling Pollution

More than £30 million is spent each year in Britain on the treatment of sewage and industrial waste water, according to the report of the Water Pollution Research Laboratory of the Ministry of Technology for 1966 (HMSO, 15s. 6d.). About half of the laboratory's resources are concerned with various methods of treatment of wastes, but other work includes a study of the effects of pollution on rivers and estuaries and the During 1966, the last of these was the coastline. largest single project; the object was to study the influence of environmental factors on the rate of dispersion of sewage discharged into the sea by coastal authorities. To do this, physical dispersion of liquid sewage has been followed using a radio-tracer, bromine-82. Bacteriological examinations of sea water samples have also been undertaken. In this way, it is hoped to provide an improved basis for choosing sites for discharge of sewage into the sea and for deciding on the degree of treatment required before discharge.

The control of aquatic weeds such as Elodea canadensis, Myriophyllum spicatum and Zannichellia palustris costs river authorities some £300,000 each year; the use of a proprietary herbicide is now being investigated for this purpose. An important and continuing line of work at the laboratory is the determination of the effect of pollution on fisheries—the toxicity of zinc to trout eggs, for example. Results of research have shown that sudden rises in temperature increase the sensitivity of trout to phenol and toxicity of phenol to rainbow trout also increases with salinity.

Studies designed to improve the performance of unit processes used in the treatment of domestic and industrial waste water have formed an important part of the laboratory programme. In addition to conventional methods, a new method of treating sewage has been developed which involves wet oxidation at high pressure. The contribution which protozoa make in the activated sludge treatment of sewage has also been followed; it seems that these organisms bring about a marked clarification of the effluent.

The treatment and disposal of sludge present more difficulties than almost any other waste treatment operation. In the 1965 laboratory report, it was pointed out that in some sewage the concentration of synthetic detergents had risen to a level which caused acute inhibition of sludge digestion: digestion can now be restored by the addition of a long-chain amine which causes precipitation of the detergent, and an experimental study of twenty-two new detergents has been carried out.

Aid by Modelmaking

THE development of econometric models has offered economists a better chance of making the right decisions. By designing quantitative models which

behave like the economy of the country concerned, it should be possible to assess more precisely the effect of small changes—in tax structure, age distribution. birth rate, or the supply of trained manpower. The history of the past three years of British economic policy indicates the sort of errors it might then be possible to avoid.

The Organization for Economic Co-operation and Development has now attempted to apply the same sort of reasoning to development assistance (Quantitative Models as an Aid to Development Assistance Policy. OECD, 1967). The sorts of questions which need answering are concerned with the effects of decisions about aid on the development of the country concerned. Would the development plan be overturned by a 10 per cent reduction in aid? Should the transport sector be developed at the expense of primary production How would changes of birth rate or migration influence economic progress? One difficulty, of course, is that econometric models are only as good as the data that go into them, and most underdeveloped countries are short of reliable statistics-often, the OECD expert group reports, the records include a quantity of miscellaneous information and statistics, without combining them into any coherent pattern. Despite this, the expert panel went on to assess how valuable the models might be.

It is clear from the start that the notion of a comprehensive model which could provide an answer to every question is unrealistic. The solution to this, according to Professor Chenery of Harvard University, and a member of the panel, is not to make the model more complicated, but to design instead a set of related sub-models to carry out the more detailed work. The group considered two models of the Pakistan economy. one prepared by Professor Tims at Harvard, and the other by Professor Chenery. The models take as one fixed point the desire by the Pakistan government to end foreign aid by 1982. Interestingly, the model reaches different conclusions from the planners in Pakistan; they assumed that aid would fall steadily as a proportion of GNP from 8 per cent in 1965 to 1 per cent (representing enough to cover external interest and dividend payments) in 1985. But the model shows an increase in aid in the early period, to a peak of 10 per cent in 1975, and then a fall to zero by 1982. This is because in the early period heavy investment is needed to produce rapid growth in the economy: demand for capital therefore exceeds what can be supplied from home resources, although 24 per cent of the growth in GNP would be saved. Demand for foreign capital therefore increases in the short run. After 1976, the emphasis would shift to the task of import substitution, or increasing exports, either of which would have the effect of improving the balance of payments. Total investment falls, and can thereafter be financed from Pakistan's own resources. After 1983, the model predicts self-sustaining growth, with sufficient investment to prevent imports from outrunning exports.

Industrial Biology

THE Institute of Biology last week held a conference on "Improving the contacts between industry and university". More than a hundred people settled into the comfortable orange seats of the Royal Society's

large lecture hall to hear ten speakers and some lively discussion, which frequently echoed the kind of discussion familiar in physical science since the publication of the Swann Report. Professor M. M. Swann himself introduced the morning session with the thought that for a long time biology had been "small, cheap and neglected", but that industrial biology is now growing rapidly. But it is not clear whether or not there is a shortage of biologists in industry, and no official analysis of the situation has yet been made. From remarks made by industrialists and academics, however, there appears to be room for more communication and co-operation. Some university departments, for example, had found that industrial budgets are so tied up that negotiations at board level are required to obtain small sums of money for a research project which in the long run could save thousands of pounds for the company. Some industrialists, on the other hand, when allotted money to pay for research in outside bodies such as universities, could find nobody who would take on particular projects. If graduates are reluctant to enter industry, some academics think it is because industry is not attractive enough, while some industrialists believe the universities are giving their students the wrong ideas.

Sandwich courses are one answer to this problem. Professor L. Broadbent of Bath University of Technology favours the thin sandwich, when the students spend alternate periods of six months in university and different industries, thereby gaining a wide variety of experience before coming to decide on a future career. Employers favour thick sandwiches, as they can give the student a worthwhile project during the year, but this long time away from university can easily disrupt academic studies.

Mr F. R. Reavell from Unilever described the difficulties of recruiting suitable biologists for industry. In 1966 there were 1,500 biologists in industry, most of them specialists. Mr Reavell saw the problem in terms of training "the right number of the right specialists for the few jobs". He wondered if the Institute of Biology could run a comprehensive appointments service.

Speaking of industrial biologists as honorary lecturers, Dr D. J. D. Hockenhull of Glaxo Ltd. said the difficulty came in "knowing what the students know", but lectures by industrial biologists can be of great value in communicating enthusiasm for the subject. Professor E. B. Chain of Imperial College discussed the question of academic biologists as consultants to industry. general," he said, "the situation is fairly satisfactory, and is improving." He believes the idea that fundamental and applied research are different is "a red herring". In his view there are only two types of research—"useful and useless". He suggested that a biological committee should be set up, possibly within the Science Research Council, to discuss and select long term research projects of industrial interest. Academics could then be approached and government money could be used to put the ideas into action. Dr A. Spicer of the Rank Research Centre described how he uses consultants in his research projects. Biologists are involved in the "marketing and economic implications" of a scheme and are therefore part of the team, instead of merely being outside observers.

Some of the difficulties faced by staff in moving between industry and university were mentioned by Professor P. W. Brian. The two groups are too often "mutually suspicious", and cherish illusions as to the way of life of the other. Dr W. F. Jepson brought in the practical factors involved when such a move is made. Security of tenure in university posts was weighed up against higher pay in industry. There would be more movement between industry and universities if pensions were transferable.

Parliament in Britain

Libraries

LORD WINTERBOTTOM, Parliamentary Secretary, Ministry of Public Building and Works, acknowledged that the National Reference Library for Science and Invention formed part of the British Museum Library, and that its future arrangements would therefore be examined by the small independent committee which the government was setting up to investigate the national libraries. Alternative sites in the Central London area were being discussed, to see if they could provide whatever is needed after the committee reports. On November 30, in the House of Commons, the Secretary of State for Education and Science, Mr P. Gordon Walker, said he hoped to announce the composition of the committee soon. He hoped the committee would recommend that the library should be sited in Central London, but added that the government's decision on the Bloomsbury site was final. He would resist any attempt to move the National Lending Library for Science and Technology to London or to the Home Counties. (Oral answer, House of Lords, November 28.)

Skylark

MRS S. WILLIAMS, Minister of State at the Department of Education and Science, said that the Science Research Council's Skylark sounding rockets which were launched at Woomera as part of the jointly financed Anglo-Australian programme cost the United Kingdom £175,000 in 1966-67. The cost in this country of the rockets, including research and development, was £531,000 in 1966-67. (Oral answer, November 30.)

Food Additives

MR S. HAY, Joint Parliamentary Secretary at the Ministry of Agriculture, Fisheries and Food, gave details of the Food Additives and Contaminants Committee (chairman, Professor R. A. Morton) and the Pharmacology Sub-Committee (chairman, Professor A. Kekwick). Mr Hay said that the Minister of Agriculture and the Minister of Health asked the Food Additives and Contaminants Committee for advice when additives were used or proposed for use in food. This committee, in conjunction with the Pharmacology Sub-Committee, then took into account all the data available in this country and internationally. (Written answer, November 29.)

Wash Barrage

MR A. GREENWOOD, Minister of Housing and Local Government, said that he was considering very carefully the suggestion of the Water Resources Board for a desk study to assess the scope for water conservation in the Wash and to appraise the case for a full feasibility study. Mr Greenwood asserted that the Wash Barrage proposition would cost about £90 million more than conventional methods, but added that the question would not be considered in isolation. (Oral answer, November 28.)

Cost of Working

A new study has defined the rate at which research expenditure is increasing.

A DETAILED study of the continually increasing cost of scientific work at several scientific laboratories, some public and some at universities, has now been published by the secretariat of the Council for Scientific Policy. The document, The Sophistication Factor in Science Expenditure (HMSO, 6s.) is the first of a series of studies commissioned by the council. Although the study seems to have shown that the variation of the rate of increased costs from one kind of establishment to another is far too great for there to be a rule of thumb applicable right across the board, with the result that the making of science policy cannot be left to men with slide rules, the analysis of expenditure which makes up the bread and butter of the report will certainly provide the heads of university departments with a useful yardstick for deciding whether they are spending too much-or too little.

The study has been concerned with a total of sixteen laboratories—nine research stations operated by the Ministry of Technology, the National Institute for Medical Research, the Rothamsted Experimental Station, the Atomic Energy Research Establishment at Harwell, the Central Veterinary Laboratory of the Ministry of Agriculture, the chemistry department at one university and the geology and zoology departments at another. The study begins by pointing out how difficult it must be to disentangle the true cost of increasing sophistication of equipment used in research from other causes of variation from one year to another—changes in the proportions of staff of various grades, natural growth and even such phenomena as inflation.

To allow for these and other factors contributing towards the total cost of a laboratory, the study begins with the statement

F/N = B + W + A

where F is the annual budget, N the number of scientific researchers, and B, W and A the cost per individual researcher of buildings, wages and apparatus respectively. One cause of increasing costs from year to year is the "desire of workers to be better accommodated" as well as the usually increased cost of housing complicated equipment. It must also be reckoned that the salary bill of a predominantly youthful establishment will tend to rise quickly because of the effects of built-in salary increments. For each of the three terms on the right-hand side of this equation, the study has assumed a separate sophistication factor. The last of the three terms, for example, is written as

$$A = A_0 I_A R_A$$

where A_0 is the cost of apparatus per year per worker at the beginning of some period, I_A is a factor which represents growth due to monetary inflation and R_A is the sophistication factor representing the increasing complexity of scientific equipment.

The chief conclusion of the report is that the increasing cost of equipment is the principal cause of rising budgets in the universities and the public laboratories. For institutions in which exceptional considerations do not inflate costs unpredictably, and where there is no natural growth, the cost of research (for each scientifically qualified man and woman) may be

expected to increase by between 2 and 5 per cent a year. The report emphasizes that this range of figures is merely a pair of brackets, and that some of the laboratories included in the survey have revealed rates of growth outside these limits.

Universities seem to have experienced the most rapid increase of growth in the cost of equipment, at least if the three university departments included in the survey are a reliable guide. For one chemistry department, for example, the staff grew at 7.2 ± 0.4 per cent a year during the 8 years from 1958, but the cost of major equipment (each item exceeding £100) increased by an average of 27 per cent a year during the same period. The corresponding figures for the public laboratories range between essentially zero (for the National Engineering Laboratory) to 27 per cent (for the National Institute for Medical Research). The rate of growth of expenditure on major items of equipment in the zoology department of the second university worked out at 8.9 per cent, but the geology department had increased its budget for major items of equipment by 25 per cent a year over the same period. These figures are at current prices—in other words, they are not corrected for inflation.

The correction for inflation necessarily entails that the survey should rely on published information about the general increase of costs in the construction industry, for example. The average annual increase of construction costs, for example, was taken as 2.3 per cent. It is calculated, on the basis of pay scales in the scientific Civil Service, that the inflation of salaries during the period 1958-65 worked out at 6.5 ± 0.5 per cent a year. At the same time, the effect of inflation on prices of equipment and machinery seems to have increased by between 3.0 and 3.5 per cent a year. These figures are intended merely to represent increases of money costs arising from monetary inflation. They are, in other words, the basis of the corrections which must be applied to the annual increase of the budget of a laboratory before the true cost of sophistication can be calculated. It is nevertheless interesting and important that the buoyant trend of scientific salaries should have been so conspicuous in the past few years.

When inflation is allowed for, the increasing sophistication of the scientific labour force, chiefly expressed by the tendency for the comparative numbers of supporting staff to increase, seems to have varied widely from one laboratory to another, but to have been not too different from 1 per cent a year. According to the report of the survey, the effect on real costs arising from the way in which a youthful labour force wins rapidly increasing increments is more important. and may account for an annual increase of real costs of about 2.5 per cent a year.

The report emphasizes that this conclusion is tentative, as is the statement that "such evidence as there is suggests a sophistication factor of 2.5 per cent a year for construction costs". Minor items of equipment are considered to cost an extra 3.0 ± 1.0 per cent a year in real terms, but the secretariat of the Science Research Council has shrunk altogether from attempting to define a sophistication factor for major items of equipment. In the period covered by the review,

expenditure under this heading seems to have varied markedly from one laboratory to another. Where the rate of expenditure on major items of equipment seems to have been about £100 per head per year, the rate of spending for major equipment may have been as much as 23 per cent. Where expenditure worked out at three times as much, however, the annual increase of expenditure might typically be about 9 per cent a year.

Although the authors of the report have been quite properly concerned with the way in which the changing character of scientific research is likely to bring in its train increases of costs, it is inevitable that those who read the document will pay at least as much attention to the absolute costs of running various departments. The "nine 'establishments within the Ministry of Technology and the Atomic Energy Research Establishment at Harwell will thus inevitably excite the interest and the envy of those who work elsewhere. On paper, at least, the AERE is the most lavishly endowed, no doubt because of the cost involved in building and refurbishing equipment associated with nuclear reactors. In 1965-66, the cost of the establishment worked out at £14.57 million, equivalent to £19,663 for each scientifically qualified member of the staff. In the nine stations transferred to the Ministry of Technology from the old DSIR, the average cost of a year's work by a scientifically qualified researcher worked out at £15,148. These figures are much greater than those applicable in other kinds of laboratories. some of which are referred to in Table 1.

Table 1. Costs of running british research establishments in 1964-65 in £ per qualified researcher

Establishment	Salaries	Equipment	Buildings	Total
Min-Tech labs.	8,096	2,660	4,167	15,148
NIMR	6,701	1,260	583	8,590
Rothamsted	4,860	542	1,219	6,888
AERE*	10,439	5,796	3,428	19,663
	* For 1	965–66.		

The figures in the report which indicate university expenditure on research and development are not comparable with these, chiefly because of the difficulty of deciding how to apportion the cost of buildings and services to the research which is carried on in university departments. It is also important that the cost of salaries attributable to the research in different public laboratories does not reflect great differences in the individual salaries paid to research workers. Although some laboratories seem to pay better salaries than others, the most marked difference between them is the extent to which the efforts of research workers are supported by the efforts of others. Thus the ratio of total staff to scientific staff varies from 4.65 at the National Institute for Medical Research and 3.77 at Rothamsted to 8.22 at the Atomic Energy Research Establishment at Harwell. The Central Veterinary Laboratory at Weybridge boasts of 2.6 technical staff for each researcher, but the record of the university departments is even less cheerful, even when research students are not counted among the academic researchers—the convention followed in the report.

Although the amount of money being spent on running the laboratories has increased absolutely over the years, and although the cost of equipment has often increased quite sharply, it does appear that the greater part of the increasing cost of operating scientific laboratories has been swallowed up by inflation. Table 2

shows the way in which the percentage rates of growth in recent years are almost entirely offset by the percentage increases in each year which must be attributed to inflation.

	Table 2	2	
	Apparent growth rate per scientist (%)	Inflation (%)	Real growth rate (%)
Min-Tech labs.	6.0 ± 0.5	4.9 ± 0.5	1.0 ± 0.7
NIMR Rothamsted	$\begin{array}{c} 8.6 \pm 1.3 \\ 9.6 \pm 0.8 \end{array}$	$\begin{array}{c} 5.9 \pm 0.5 \\ 5.9 \pm 0.5 \end{array}$	$2.5\pm1.4 \\ 3.5\pm0.9$
AERE	$4 \cdot 3 \pm 0 \cdot 6$	$5 \cdot 0 \pm 0 \cdot 5$	0.6 ± 0.8

Precisely what implications these figures will have for the development of policy in science it is too soon to know. The report of the survey itself says that there is a great need to accumulate further information on this and other subjects. Long before that has been done, the British Government may choose to interpret information like that contained in Table 2 as a proof that, if only government departments are tough enough, even the most powerful laboratories can be made to draw in their horns.

The report will also be followed carefully by those seeking evidence of the trend of university expenditure in the past decade or so. The three university departments covered by the survey seem to have kept successfully ahead of the government laboratories during most of this period. The department of geology included in the survey, for example, increased its staff from 8 to 15 between 1955 and 1964, and the numbers of research students on the books increased from 5 to 14 during the same period. Technical staff increased in numbers even more rapidly, from 5 in 1955 to 18 in 1964. This implies an annual rate of growth of the research force at the laboratory of 10.9 per cent a year, but average salary during the same period increased from £1,051 per researcher per year to £1,837 per researcher per year. These figures include the cost of technical assistance (but research students are counted as researchers). The most rapid increase in the department's salary bill is attributable to the salaries of technical assistants—a three-fold increase of the labour force was accompanied by a six-fold increase of salary.

Much the same pattern seems to have been followed at the zoology department at the same university, although this has not grown as quickly in numerical terms. One striking feature of the figures which are provided in the survey is the modesty of the sums available for travel by the academic staff. zoology department, for example, spent £239 on the travel of 27 research people in 1955 and £675 on the travelling expenses of 49 people a decade later. Although the report on sophistication has made no explicit attempt to work out the sophistication of these smaller components of the budget, it is hard to believe that the rates of increase implied by the figures obtained from two university departments can have allowed the academics concerned to keep pace with the growing cost of travel, let alone with the growing need among research people to attend research conferences in ever more distant places. Academic readers of the report will also be impressed with the comparatively modest scale on which university departments appear to be able to provide themselves with equip-

NEWS AND VIEWS

New Era for Salk Institute?

THE appointment of Mr Joseph Slater as president of the Salk Institute for Biological Research has been welcomed inside the institute as well as in the wider world. For one thing, Mr Slater has won a distinguished reputation in his work with the Ford Foundation in the past few years, and has in particular been concerned with a great many of the schemes which the foundation has devised for the creation in Europe of new kinds of institutions. One of his associates the other day described him as a splendid intellectual entrepreneur, and it seems commonly to be agreed that Mr Slater is an easy person to work with. All of this suggests that he may be just the man to give the Salk Institute what it has most conspicuously lacked in the past two years—a strong sense of direction, a firm administration and an air of confidence, which is not the same thing as smugness. His appointment, which becomes effective in the New Year, also raises important questions about the functions of independent research institutes like that which Dr Jonas Salk has built up in California. What place is there in the modern world for establishments like this which are not directly linked with universities?

It is important to separate the troubles which have assailed the Salk Foundation from the more general questions of how independent institutions should be organized and co-ordinated with the rest of the intellectual community. The most obvious problems in the short history of the institute have been money troubles, and most of these derive from the way in which the institute elected to sink more than it could reasonably afford on the superb buildings which now grace La Jolla in southern California. By all accounts, these edifices have cost the best part of £20 million. More seriously, they have consumed much of the capital fund originally provided by the National Foundation as an endowment intended to provide the institute with a regular income big enough to keep the laboratories ticking over. In these circumstances it has been understandably difficult for people to plan ahead.

How will these circumstances be changed by the arrival of Mr Slater? To begin with, he seems firmly convinced that the institute can resume the growth which was expected when the new buildings were planned only a few years ago. Moreover, he plans to graft on to the work now carried out at La Jolla, most of it in fields somehow related to molecular biology, some work which may be considered more properly to belong to the social sciences. The likelihood that the institute will increase its stake in neurophysiology in the years ahead has been talked of seriously for some time. Now there is also a chance that it will find itself engaged in a much wider field of activities related to the interaction between people and their environment. It is only proper to acknow-

ledge that these developments are entirely in line with the original conception of the institute which Dr Salk outlined at the foundation of his establishment, and that Dr Salk will continue as director of the institute after Mr Slater arrives. The difference now, however, is that Mr Slater may be better placed than anybody else at the Salk Institute to recruit the kinds of people who are capable of distinguished work in fields like this. On all these counts, it is entirely understandable that his transfer to the Salk Institute will be welcomed.

There remains the issue of how institutions like the Salk Institute can be expected to contribute to intellectual life, in the United States and elsewhere. That they provide an opportunity for distinguished scholars to pursue their own activities is beyond dispute, but there is a constant danger that they will serve to isolate the same people from what happens at the universities and elsewhere. Badly managed, ivory towers like this can even protect the work of some research groups from the fierce blast of criticism which is elsewhere found to be a necessary assurance of quality. The problem is how to strike a balance between the benefits and the hazards of isolation. The Salk Institute is fortunate in that it is placed within the thriving intellectual community at La Jolla. The system whereby a number of part-time fellows, all of them distinguished people, serve both as intellectual catalysts and talent scouts, is another protection against isolation. Yet these are mechanisms which demand constant attention. The danger at La Jolla is that the passage of time would erode the determination of the men in charge to keep the institute on its chosen course. In the circumstances, it will be a benefit and not a handicap if Mr Slater can somehow engage the institute more fully in matters which go beyond the boundaries of its present work.

Machine Tools

The modern investigation of machine tool problems did not start until 1880, although Henry Maudsley had earlier been concerned with perfecting the production of screws. This was one view introduced by Mr K. R. Gilbert on November 29 when he spoke to the History of Science discussion group at the Royal Institution. Maudsley, who was born in 1771 and who set up his own workshop in London in 1797, realized that an accurate screw is fundamental to the production of accurate machine tools. Maudsley's masterpiece was a screw five feet long, two inches in diameter and with a total of three thousand turns. On it was screwed a nut twelve inches long with six hundred threads. It was used in an apparatus for dividing scales for astronomical and other metrical purposes. Maudsley favoured a mechanical method for producing

screws, and his beautifully made apparatus provided with fine adjustment for helix angle and knife and cutter feed still exists.

The most significant development in the control of machine tools this century is hydraulic control. The idea of controlling a machine tool hydraulically had been put forward in the United States in 1893 by C. M. Conradson, but no great advances were made until the work of the Oilgear Company in the mid 1920s. The advantages gained over mechanical control were flexibility, infinitely variable speed, avoidance of shock on reversal of motion and constant pressure on the cutting tool. Hydraulic control also led to the application of servo mechanisms to machine tool control. Watt's steam engine centrifugal governor is the earliest example of this. Techniques of servo control have been applied to the most advanced system of machine tool control-numerical control. This permits continuous path machining and works straight from the dimensions and curves specified by the designer. The value of numerically controlled machine tools is in batch production: indeed, numerical control was conceived as a means of simplifying medium and small run production such as that encountered in the aircraft industry. This research was carried out over a period of five years starting in July 1949 at the Servomechanisms Laboratory of the Massachusetts Institute of Technology by Professor Gordon S. Brown and twenty-six co-workers.

Hyperbaric Oxygen

from our Microbiology Correspondent

Much has been written on the subject of oxygen toxicity since the classic studies of Bert in the 1870s, and many micro-organisms are now known to be affected adversely by increased oxygen concentrations. Aerobic bacteria can frequently tolerate partial pressures of exygen of up to 2-10 atmospheres, but raising the hydrostatic pressure drastically increases their sensitivity to oxygen. The growth of aerobic bacteria is little inhibited at pressures of 50-100 atmospheres provided that the medium contains normal levels of oxygen, that is, less than 10 µg/ml. At higher pressures, however, the lag phase and generation time are prolonged and the maximum population is depressed. Furthermore, with the exception of barophilic species, increasing the pressure to 400-600 atmospheres inhibits growth, and extended compression often sterilizes the culture. ZoBell and Hittle (Canad. J. Microbiol., 13, 1311: 1967) have found that hyperbaric oxygen concentrations (35-105 $\mu g/ml$.) are similarly lethal at pressures as low as 4 atmospheres. Even barophilic marine bacteria such as Pseudomonas perfectomarinus, which will grow at pressures of more than 600 atmospheres if the medium is low in oxygen, are susceptible to hyperbaric oxygen at a pressure of 5 atmospheres. ZoBell and Hittle reiterate that a disturbed redox balance, oxidation of thiol or disulphide enzymes and an accumulation of toxic oxidation products are among the factors contributing to hyperbaric oxygen toxicity.

Recent work with euglenoid algae has defined more precisely some of the repercussions of hyperbaric oxygen on metabolism. Bégin-Heick and Blum (Biochem. J., 105, 813; 1967) discovered that cell division in Astasia longa was inhibited when culture

aeration with air + carbon dioxide (95:5) was replaced by an oxygen+carbon dioxide (95:5) mixture. Growth was resumed at the normal rate after re-gassing with air + carbon dioxide and both the initial inhibition and the post-oxygen recovery occurred very rapidly. In this system the toxic effect of oxygen is obvious even at atmospheric pressure. Assay of mitochondrial enzymes showed that succinate-cytochrome C oxidoreductase, NADH-cytochrome C oxidoreductase, succinate dehydrogenase and the succinate oxidase system had greatly reduced activities compared with preparations from cells grown in air+carbon dioxide. The oxygen effect can be related, therefore, to a mitochondrial lesion, and the 75 per cent fall in succinate dehydrogenase activity is entirely responsible for the reduced activities of the succinate-cytochrome Coxidoreductase and the succinate oxidase system. The fact that NADH-cytochrome C oxidoreductase is also inhibited by oxygen is indicative of a second site of action in the electron transport chain.

Blum and Bégin-Heick (Biochem. J., 105, 821; 1967) have made the interesting observation that the closely related Euglena gracilis var. bacillaris is only sensitive to hyperbaric oxygen when grown in a lowphosphate (20 μ M) medium with ethanol as the carbon source. Euglena under these conditions showed a decreased rate of respiration and an inability to resume growth when phosphate was replenished. This oxygen toxicity was far less marked when the alga was grown on glucose. Like Astasia, oxygen sensitized Euglena also had decreased activities of succinate- and NADHcytochrome C oxidoreductases and succinate dehydrogenase when compared with cells grown in a highphosphate (20 mM) medium. Although the differentiating action of hyperbaric oxygen plus low phosphate on cells grown with ethanol and glucose may reflect different sensitivities of endogenous and exogenous oxidative pathways, the mechanism of the sensitizing effect of low-phosphate as such still has to be resolved.

Proteins and Ligands

from our Molecular Biology Correspondent

THE study of the behaviour of ligands has been a promising approach to the difficult problem of observing and interpreting localized conformational changes in proteins, associated, for example, with enzyme activity. Ligands may in some cases compete directly with a substrate at an active site, or they may stabilize one conformational state of the protein with respect to others for which they have lower affinities.

An interesting example of the latter phenomenon-comes from Markus et al. (J. Biol. Chem., 242, 4402; 1967), who have studied the binding of anionic dyes to-serum albumin—a protein chiefly noted for its propensity to bind an extraordinary variety of small molecules of different kinds. The albumin with and without these ligands was then used as a substrate formitive different proteolytic enzymes, and in all cases the bound ligand was found to inhibit digestion. From the stoichiometry of the binding, it appears that onlytwo dye molecules need to be attached to produce the full effect. There are also appreciable changes in the distribution of the products of limited proteolysis. The most attractive explanation is that the protein exists in a state of equilibrium between two or more

conformational isomers, and that the equilibrium is displaced by the added dye in favour of the form to which it most avidly binds. In the present case, this form is evidently one in which the susceptible peptide bonds are relatively unavailable, or in which the structure is comparatively rigid and inflexible. Markus and his co-workers have previously recorded a case in which the binding of a ligand renders a protein more prone to proteolysis, and the converse presumably holds in their latest work.

Several examples of the binding of dyes at or near the active sites of enzymes have recently been reported. The latest of a number of studies by Glazer (J. Biol. Chem., 242, 4528; 1967) concerns the binding of the anionic dye, Biebrich scarlet, to chymotrypsin. It has proved generally true, as revealed notably by X-ray studies on enzymes, that active sites are situated in crevices, giving on to the predominantly non-polar interior of the molecule. Equally, most organic ligands which are capable of binding strongly to a protein evidently seek an essentially non-polar environment (as shown, for example, by dyes which exhibit fluorescence only in substantially non-aqueous solvent systems, and which become fluorescent when they bind to proteins). Thus it is not surprising that a pattern is beginning to emerge of binding of many such small molecules specifically at active centres. Several cationic dyes have been found to bind at the active centre of chymotrypsin, and it is interesting that Biebrich scarlet, being anionic, binds with comparable affinity. The binding can be followed by changes in the absorption spectrum of the ligand. The dye competes with, and is displaced by, substrates and competitive inhibitors. It does not bind to chymotrypsinogen, which suggests that here the active site is occluded.

Another application of dye-binding is due to Koshland, who uses a covalently attached chromophore as a so-called "reporter" for events involved in the binding and conversion of substrates. Hille and Koshland (J. Amer. Chem. Soc., 89, 5945; 1967) have bound a compound containing the highly medium-sensitive nitrophenyl chromophore to methionine-192 of chymotrypsin, which is three residues along the chain from the serine of the active site. The activity of the enzyme is preserved, and one can then observe the perturbation of the nitrophenyl spectrum, when for example the pH is changed. The magnitude of the perturbation, in fact, follows a titration curve, with a pK of 7. Addition of substrate eliminates this effect, and it is suggested that the bound chromophoric group is pushed out of the way. The speculation is that the ionizing group is the active-site histidine, and if this is true its pK is thereby established. It must be hoped that a comparison of data of this kind with the environment of the residues in question in the crystallographic structure will ultimately lead to general correlations about their properties, and that this will help in interpretation of the mechanism of catalysis.

Chromosome Breakage

from our Cytogenetics Correspondent

Radiation and many chemicals used in cancer chemotherapy and as antibiotics cause chromosome breakage. Breakage is a result of the disruption of DNA synthesis or some other disturbance of chromosome organization and so interest in induced chromosome breakage lies in what this can say about the structure and chemistry of chromosomes. One important question is whether chromosomes in different phases of the cell cycle are equally sensitive to damage. In both animal and plant cells there is evidence that chromosomes are more sensitive to certain agents during the G_2 phase of interphase (that is, between the DNA synthetic stage, S, and mitosis) than during the S or pre-S (G_1) phases of Methyl coumarin has been shown by Ronchi and her colleagues (Mutation Res., 4, 615 and 791; 1967) to cause most breaks to bean and onion chromosomes during G_2 as well as to prolong this phase. They also showed that exposing roots previously treated with methyl coumarin to chloramphenicol causes an increase in the number of breaks, and they interpret this as evidence that protein synthesis is required to repair breaks. Breaks are more numerous in the presence of chloramphenicol because many of the breaks induced by methyl coumarin have not been allowed to heal. The requirement of protein synthesis for healing breaks is not a new idea, but it does pose some obvious questions. Is it a repair enzyme or a protein of chromosome structure that is synthesized? And if it is an enzyme, can differences in its activity account for differences in apparent sensitivity of chromosomes during the cell cycle?

Scott and Evans have also shown (Mutation Res., 4, 579; 1967) that chromosomes of bean at G_2 are most sensitive to X-rays and, further, that chromosomes at different points in the G_2 phase differ in sensitivity. Similarly, Dewey et al. (Int. J. Radiat. Biol., 12, 597; 1967) showed that Chinese hamster chromosomes sustained 2.5 times more chromosome damage in G_2 than in S. In their experiments the chromosome damage was self inflicted as the chromosomes were allowed to incorporate a high level of radioactivity in the form of tritiated thymidine.

Breaks in chromosomes could be caused by interference with nucleic acid metabolism rather than a physical shattering of the chromosome thread. This at least seems to be one of the effects of 9- β -D-arabino-furanosyladenine (ara-A). Its triphosphate has been shown by Furth and Cohen (Cancer Res., 27, 1528; 1967) to be able to inhibit DNA polymerase of mammalian cells (but not that from cells of the bacterium Escherichia coli) and may also inhibit the nucleotide reductase system. But ara-A is able to cause breaks at G_2 ; could it be that there is some DNA synthesis not detectable by conventional methods during G_2 that all these agents inhibit?

What of induced chromosome breakage in meiotic cells? Westerman (Chromosoma, 22, 401; 1967) describes the effects of irradiating meiotic chromosomes during spermiogenesis in male locusts. He found that cells irradiated during the S phase of meiosis showed chromosomes with a lowered chiasma frequency at the subsequent metaphase, while cells irradiated at diplotene or in the S phase of premeiotic mitosis showed an increase in chiasma frequency. The chiasma frequency was most changed in the long chromosomes while that of the short chromosomes was hardly changed at all. It is tempting to speculate on the role of chromosome breakage on the time and mode of chiasma formation, but only further experimental work will allow concrete fact to replace speculation in this perplexing problem.

Superconducting Magnets in High Energy Physics

P. F. SMITH
D. B. THOMAS

Rutherford High Energy Laboratory, Science Research Council, Chilton, Didcot, Berkshire Magnets play a large part in the study of elementary sub-nuclear particles. Advances in the technology of superconducting magnets suggest that these magnets will be an important factor in the design of future accelerators, and their associated experimental equipment.

In recent years, in the high energy physics laboratories of the world, a large number of elementary sub-nuclear particles have been discovered by studying the interactions produced when suitable targets are bombarded with beams of charged particles from giant accelerators. These accelerators and their associated equipment use experimental techniques of the utmost sophistication, and magnetic fields are the basis of most of these techniques, because the transverse force on a charged particle moving in a magnetic field constrains it to describe an arc of a circle.

This simple effect is employed in a variety of ways. For example, during acceleration in a proton synchrotron the particle beam is confined to a closed circular orbit by a ring of powerful electromagnets. After acceleration, the primary beam can either be extracted from this circular orbit and directed at a target, or made to impinge on a target in the machine. In both cases, secondary particles are produced and these have to be transported to experimental equipment often situated one or two hundred feet from the accelerator. Here again, magnetic fields play a prominent part, for, in beam optics, magnetic lenses provide the necessary focusing, and bending magnets can steer the particles along the desired paths. In many experiments, separated beams, consisting only of particles of the desired type and momentum, are selected from the wide spectrum of secondary particles. For such beams a bending magnet with collimating slits provides the momentum selection in an analogous fashion to a glass prism in an optical spectrometer. In the nuclear experiments themselves, the momenta of particles created by interactions within the experimental apparatus can often he determined by measuring the actual curvature of the paths of the particles in a known magnetic field. An elegant example of the type of apparatus is the bubble chamber, where the curved tracks of charged particles can be seen as lines of minute bubbles which the particles have nucleated in a superheated liquid, for example, liquid hydrogen. The entire liquid volume is immersed in a high magnetic field, and measurement of stereophotographs of the curved tracks makes it possible to calculate the momenta of participating particles. There are also a number of smaller scale applications which use a magnetic field in a fundamental manner, such as measuring the magnetic moments of particles and the polarization of protons in a target.

It is clear that any technological breakthrough in the generation of higher or more stable magnetic fields would have a substantial impact on the instrumentation of high energy physics. This would be particularly true if economies also resulted either in terms of reduced capital outlay or running costs, for in recent years elementary particle physics has become so expensive that it can only be pursued by the larger countries or by groups of smaller countries collaborating in the funding of international laboratories. So far, virtually all the requirements for magnetic fields have been fulfilled using conventional electromagnets consisting of water-cooled copper conductors, usually wound on steel yokes to reduce power consumption and to shape the magnetic field. The value of the magnetic field is usually in the range 10–20 kgauss;

above this, the steel saturates and power requirements increase sharply. Because of this, fields in the region 30-200 kgauss, although technically feasible, have not hitherto been generally available (except in very small volumes) for purely economic reasons.

In 1961 a spectacular advance occurred with the discovery of several new superconducting alloys which, at very low temperatures, would carry very high steady currents in high magnetic fields with no dissipation of electrical power whatsoever. Previously known superconductors would only exhibit zero electrical resistance in magnetic fields typically less than a few kgauss. Using the new materials, large volumes of magnetic field of up to 100 kgauss and above could in principle be provided, free from the power limitations of conventional magnets. The potential significance of this led to development programmes of superconducting magnets being initiated in many nuclear physics laboratories, and elsewhere in connexion with other possible applications in fields such as plasma physics, magneto-hydrodynamic power generation, power transmission and energy storage for space research. The transition from this stage of promise to that of working hardware has been somewhat protracted and this has been caused largely by a number of unexpected technical difficulties which will be discussed. Considerable progress has now been made in overcoming these difficulties and it has now become feasible to construct large d.c. superconducting coils.

Already, a liquid helium chamber, 10 in. in diameter, equipped with a pair of superconducting coils giving a field of over 40 kgauss, has been used in nuclear physics experiments at Argonne National Laboratory in America, and a polarized target with a superconducting magnet has been used in experiments at the Cambridge Electron Accelerator, Massachusetts. The largest superconducting magnet yet to be successfully tested was built in connexion with a magneto-hydrodynamic programme by the Avco-Everett Research Laboratory, Massachusetts. This magnet gives a transverse field of 40 kgauss across acylindrical volume of approximately 2 ft. inner diameter and 10 ft. length. The highest field so far achieved withas superconducting magnet is 140 kgauss, in a 6 in. bore coil constructed by the Radio Corporation of America.

A measure of the general confidence invested in these new techniques can be gleaned by examining the many magnets now under construction. The largest of these is a superconducting magnet to provide a field strength of almost 25 kgauss over a cylindrical volume 15 ft. if diameter by 9 ft. high. This magnet, intended for a bubble chamber application at Argonne National Labora tory, should receive its initial test in the second half o 1968.

Present Status

In this article, a brief summary is given of the presenstate of superconducting magnet development togethe with a survey of the expected impact on high energ, physics in both the immediate future and, speculatively in the more distant future.

A superconducting magnet is essentially a coil of wir made from a superconducting alloy which is maintaine. at a temperature a few degrees above absolute zero. The current density attainable in a particular superconductor decreases with both increasing magnetic field and increasing temperature; for practical purposes it is most convenient to operate at a temperature of 4.2° K by simply immersing the coil in liquid helium. The size and shape of the coil and its low temperature enclosure vary considerably according to the application, but the principles are the same in all cases. With modern advances in liquid helium refrigeration and cryogenic engineering, making coils is now relatively straightforward even up to the larger sizes. The principal difficulties encountered to date all arise from the nature of the materials themselves.

There are, firstly, the manufacturing problems. superconductor with the highest known critical field (of over 200 kgauss) is niobium-tin, but this is a brittle compound which cannot be drawn into a wire. It has taken several years for manufacturers to develop reliable techniques for producing suitable conductors from this material, for example, by vapour deposition of a thin layer on a stainless steel tape, or by diffusing tin into niobium tape. Somewhat easier to handle are the ductile alloys niobium-zirconium and niobium-titanium which are suitable for fields up to 80 to 90 kgauss. These can be made into strong wires but require special sequences of mechanical working and heat treatment to achieve the required high current densities.

A more fundamental problem encountered with these new materials was the unexpected discovery that they behaved in an unstable manner when wound into coils. Many early magnets reached only a fraction of their design current before reverting to a resistive state. Initially this was thought to be caused by imperfections in the material arising from the manufacturing difficulties; eventually, however, the effect was shown to be caused by the discontinuous penetration of magnetic flux into the superconductor, resulting in transient heat pulses which were sufficiently large to destroy the superconducting state. In this way, small resistive regions were formed which grew rapidly and resulted in a complete collapse of the magnetic field in a few msec, often damaging the coil

by internal voltage breakdown or local overheating. This phenomenon is still not fully understood, but a variety of ways of stabilizing the materials are known in principle and are under investigation. Of these, the best understood technique is that of "full stabilization" in which the superconductor is bonded to a parallel length of low resistance normal metal, such as copper, which provides a temporary alternative path for the current in the event of a local resistive region appearing in the superconductor. The heat dissipated in the copper is carried away by the liquid helium (for which channels are provided to allow it to permeate the whole coil), so allowing the system to recover to its original state. The amount of normal conductor necessary to achieve this degree of stability, however, can be as much as ten or twenty times the amount of superconductor; this considerably decreases the current density and increases the size and weight of the coil, making it a technique only suitable for very large magnets.

More elegant "partial stabilization" techniques are being studied, in which relatively small quantities of normal metal are used to absorb the heat released by flux motion; small coils can be designed in this way simply on the basis of experience, but thorough quantitative understanding will be necessary before these principles can be applied with confidence to larger magnets. Another promising idea is to increase stability by subdividing the superconductor into finer strands, and by this means it should be possible in the future to achieve very compact high

current density coils.

Finally, there are several major mechanical and electrical engineering problems to be faced in the design of large superconducting coils. Perhaps the most significant of these is in the containing of the large electromagnetic

forces on the windings at high magnetic fields, and the necessity for protection circuits to extract from the coil most of the magnetic stored energy, in the event of an accidental transition to the normal (resistive) state.

Because of the many technical problems, and their attendant financial risks, the construction of superconducting coils is still proceeding rather cautiously. convenient indication of the size of a magnet is given by the stored energy in the magnetic field. For example, a 20 kgauss, 1 m internal diameter, coil would have a stored energy of about 10° Joules, and a 100 kgauss, 3 m diameter coil would store about 10° Joules. At the present time the largest coils built and operated have energies in the region 10⁶ to 10⁷ Joules, and cost up to about £100,000. Recent design studies, associated in particular with proposed new bubble chambers, have shown that coils in the range 10° to 10° Joules are now feasible, and several magnets of this size are likely to be completed within the next 5 yr.

So far the demand for superconducting alloys has been relatively small and has yet to justify really large scale production. Processing costs are high, with the basic metals representing only a small fraction of the overall price of stabilized conductors. As superconducting magnet technology becomes established, however, the increasing demand will decrease both conductor and engineering costs, and even larger and more powerful magnets will become possible.

Beam Transport Magnets

As already mentioned, two kinds of magnet are of particular importance in beam optics. The first, generally known as a bending magnet (Fig. 1a), provides a channel of uniform field and is used to change the direction of a particle beam and also to select particles of the required

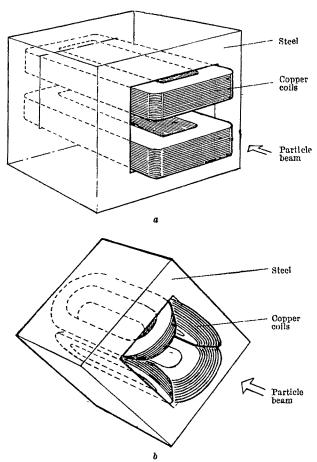

Fig. 1. a, Conventional fron-cored bending magnet; b, conventional iron-cored quadrupole focusing magnet.

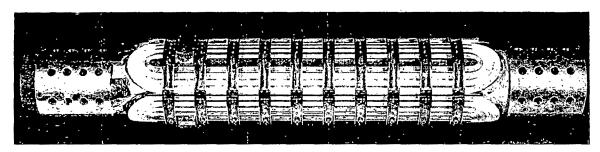

Fig. 2. Superconducting quadrupole constructed at the Brookhaven National Laboratory, USA. It is designed to produce a peak field in the range 40-60 kgauss in a channel 60 cm long by 10 cm diameter.

momentum; the second, known as a quadrupole (Fig. 1b), provides a special distribution of magnetic field to focus the particle beam.

Typically these magnets are 50 to 200 cm long, with a 10 to 20 cm aperture for the beam; costs are in the region £5,000 to £15,000, and power consumption 30 to 100 kW, for each magnet. A large accelerator laboratory requires about 150 magnets of this type, with individual stabilized power supplies. Proposed accelerators of even higher energy would require conventional beam transport magnets up to 400 cm long and 40 cm aperture, multiplying the cost and power requirements by a factor of four.

The increasing size of these magnets is caused principally by the fact that the magnetic field is limited (by saturation of the steel) to about 10-20 kgauss, and the length of magnet required to produce a given deflexion increases in proportion to the particle momentum. In this situation the use of superconducting magnets offers two possible advantages. First, the higher fields and field gradients would allow the magnet lengths and apertures to be reduced. As an example, a 10 cm aperture, 1 m long, 40 kgauss superconducting quadrupole would be equivalent to a 40 cm aperture, 4 m long, 10 kgauss iron-cored quadrupole. These more compact magnets would have many purely practical advantages, for example, in situations where a large beam deflexion is required in a restricted distance, or when it is necessary to focus a beam of short-lived particles. Second, preliminary estimates suggest that, if produced in large numbers, these smaller superconducting elements should eventually have a lower capital cost than their conventional counterparts, and should also give a considerable saving in running cost.

The practical advantages may be more beneficial at existing laboratories, where space is limited, and the increasing use of superconducting magnets should considerably widen the scope and improve the efficiency of experiments. The potential economic advantages are more relevant to future accelerator laboratories, and in any such proposals serious consideration will be given to the possibility of making the entire beam transport system superconducting, perhaps with all the magnets linked to one central helium refrigerator.

The development of these magnets is still at a very early stage. As yet, most superconducting coils have been of the simple cylindrical type, whereas for bending and focusing magnets much more complicated coil shapes are needed, to give the required field distribution accurately together with access for the particle beam. accelerator laboratories are constructing prototype versions of these magnets; Fig. 2 shows the coils of one of a series of quadrupoles constructed at the Brookhaven Laboratory in the USA. A very compact design is achieved by using high current density niobium-tin tape. Fig. 3 shows a bending magnet to be constructed at the Rutherford Laboratory during 1968. This uses a fully stabilized composite conductor of niobium-titanium and copper. Both of these will be used in actual particle beams, and will provide valuable experience in the engineering, instrumentation and operation of this type of magnet. Con-

siderable effort will be made during the next few years to study and simplify the design of these types of magnet so that they can be produced reliably and economically in large numbers.

Bubble Chamber Magnets

The new generation of hydrogen bubble chambers, now under design or construction, will all be equipped with superconducting magnets. It is the advent of this type of magnet which has made possible chambers of the size now contemplated, because the cost of powering conventional coils to produce magnetic fields of the required magnitudes and volumes would be prohibitive. It is for this reason that a paradoxical situation exists in which, in spite of the present high unit cost of superconductors, it is the largest and most expensive magnets which have the strongest economic justification.

At the time of writing there are two such large magnets under construction in the USA. Several others are at an advanced stage of planning in Europe, America and Russia. The principal parameters of the individual designs are given in Table 1. It should be noted that, while the iron yoke makes an important contribution to the central field strength in the Argonne magnet, in the CERN and Rutherford Laboratory designs the contribution is small, amounting to only a few per cent, the iron being included simply for magnetic shielding of the surrounding apparatus. An artist's impression of the proposed 1.5 m diameter high field chamber for the Rutherford Laboratory is shown in Fig. 4.

In addition to new chamber proposals, the replacement of conventional coils on many existing bubble chambers is being actively considered in order to increase the available magnetic field strength and thus increase the precision with which the momentum of the various elementary particles under study can be determined.

With these large coils, the engineering problems, which dominate the design, are principally those connected with the mechanical constraint of the massive electromagnetic forces generated by the interaction between the magnetic field and the current producing the field. In an infinitely long coil, these forces would all be directed radially. In practical coils, which often have lengths comparable with their diameter, large axial forces are also generated, particularly at the extremities of the coil where the largest radial components of field exist. Furthermore, in a bubble chamber, to allow access for the beams of particles, it is necessary to use a pair of coils separated typically by 20 cm, and these must be held apart against the powerful attractive force which exists between them. Some idea of the size of the forces is given by the following example. The pair of coils of the bubble chamber illustrated in Fig. 4 attract each other with a force of 10,000 tons, and the radial electromagnetic forces produce tensile "hoop" stresses perpendicular to the rectangular crosssection of the coil amounting in total to almost 4,000 tons for each coil.

In addition to the stabilized conductor it will therefore usually be necessary to incorporate into the coil a stronger material, such as stainless steel, to support the high stresses. In the Rutherford Laboratory's proposed 70 kgauss coil, for example, strips of stabilized superconductor will be wound into flat "pancake" coils together with stainless steel strengthening tapes, interturn insulation,

and spacers to allow helium penetration. The conductor will probably consist of superconducting strands embedded in a matrix of copper, of rectangular section about 5 cm by 0.3 cm, and will carry a fully stabilized current of 7,000 amps. Thirty-six of these pancakes will be stacked together to form two complete coil assemblies of approximate total weight 100 tons. A schematic drawing of a section of one pancake is shown in Fig. 5.

In lower field coils, such as for the Argonne bubble chamber, it is possible to omit the stainless steel altogether and rely on the copper to carry the internal forces. Furthermore, sufficient thermal stabilization can be provided by exposing only the edges of the conductor to the liquid helium; interturn helium channels are therefore unnecessary, and a more rigid coil structure can be achieved.

In the design of these large coils particular attention must be paid to the compatibility of the materials used from the standpoint of thermal contraction. In cooling from 300°-4° K, appreciable mechanical stresses can arise from local differences in thermal contraction or by uneven cooling of the whole coil. For this reason cooldown times for these coils are intended to extend over four or five days. The closed loop refrigerator must then produce several thousand litres of liquid helium in which to immerse the coils. There are suggestions, however, that stabilized coils might run satisfactorily in cold helium gas and this is being investigated. During charging of these coils to their full field, power dissipation occurs in the conductor because of induced eddy currents; because of the limited refrigeration capacity available, charging times of several hours are envisaged. In the event of an extended refrigerator failure, measures must be taken to remove the energy stored in the magnetic field and dissipate it in an external resistance. Apart from the possibility of physical damage to the coils if this energy were all dissipated locally in the coils, the overall temperature rise would be such that a further cool-down period of perhaps one day would elapse before the coil could become operational again.

All of these problems are being intensively studied at the present time; no unsurmountable obstacles have been encountered, and it can be confidently predicted that several coils of this size will be in operation by the early 1970s.

Future Possibilities

The most obvious target for speculation is the particle accelerator itself. Although many types and varieties of accelerator have been developed, the only one which seems suitable for construction on a very large scale is the alternating gradient proton synchrotron. The principal feature of the machine is an underground tunnel housing a ring of magnets which maintain the particles in a circular orbit during acceleration. The individual magnets in the ring are quite small, and are similar in type to the beam transport magnets discussed previously, except that the deflecting and focusing properties are usually combined in each magnet. The largest existing accelerators at Brookhaven and CERN give particles with energies of up to 30 GeV and have magnet rings about half a mile in circumference. A new accelerator is to be built in the United States with an energy of 200 GeV, and there is a proposal for a European accelerator of

Table 1. MAIN PARAMETERS OF HYDROGEN BUBBLE CHAMBER MAGNETS UNDER CONSTRUCTION OR DESIGN

300 GeV. The latter would have a magnet tunnel 4.5 miles in circumference, containing about 900 precisely aligned individual magnets, each 6 m long. The magnets alone will cost £16 million, and the estimated capital cost of the whole project is £148 million.

Whether the use of superconducting magnets could significantly reduce the cost of accelerators is still an unresolved question. The potential cost gain arises principally from the decreased size of the ring (because of the higher magnetic field), but because something like 25 per cent of the circumference has to be occupied by equipment other than magnets it is not yet clear how much it would really be possible to reduce the diameter. Assuming the diameter could be reduced to less than about one-quarter of that for conventional magnets, preliminary estimates suggest that there could be a significant gain in overall cost. Perhaps a more attractive idea, however, is

the possibility of converting a conventional accelerator to a higher energy. The possibility has been considered of converting the Rutherford Laboratory 7 GeV synchrotron "Nimrod" to an energy of perhaps 35–40 GeV by replacing the present 14 kgauss conventional magnet with an 80 kgauss superconducting magnet, although the competing requirement for a higher beam intensity may make this conversion difficult. As a more extreme example, a 300 GeV machine built in the near future would necessarily have to use conventional magnets; but in tensifier years' time, with superconductor technology in a more advanced stage, these might be replaced by high field magnets, thus converting the accelerator to perhaps 1,500 GeV at only a fraction of the cost of a completely new accelerator of this energy.

A serious obstacle to the development of this type of magnet is the a.c. loss in the superconductor. A synchro-

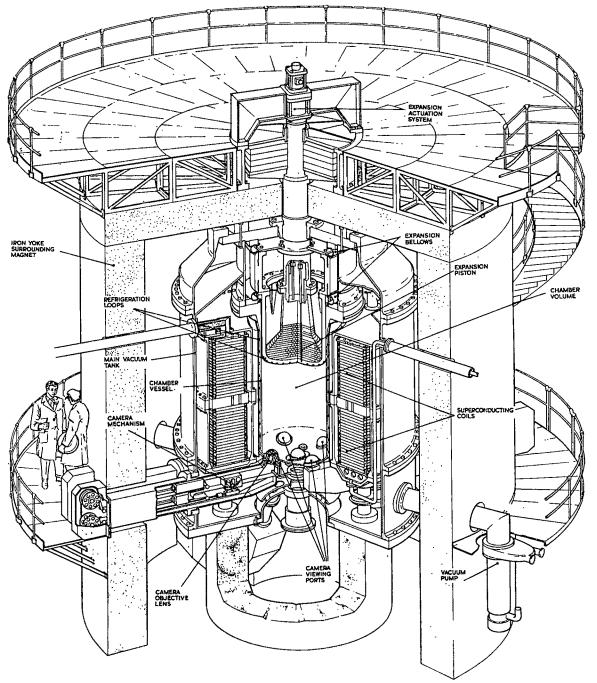

Fig. 4. Artist's impression of proposed new hydrogen bubble chamber for the Rutherford Laboratory. A pair of cylindrical colls produces a field of 70 kgauss, uniform to a few per cent, over the working volume of the chamber 1.5 m diameter by 1 m deep.

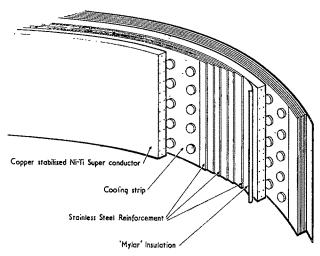

Fig. 5. Possible conductor configuration for bubble chamber coil, showing stainless steel reinforcement and interturn cooling channels.

tron magnet is pulsed, the field rising to a maximum and falling back to zero every few seconds. A fluctuating magnetic field causes heat to be dissipated in the superconducting material, and with existing conductors this would increase the refrigeration requirement to an un economic level. One possible solution is to produce a conductor in which the superconducting alloy is subdivided into filaments each about $10-20\mu$ in diameter; it can be shown theoretically that this should reduce the heat dissipated to a tolerable level. Development work along these lines has already commenced, but it is evident that it will be some years before the feasibility and long term reliability of pulsed superconducting magnets can be established with the required certainty.

A significant related problem is that a high field superconducting magnet, although physically smaller, would probably have at least four times the stored energy of a conventional magnet. It is this peak stored energy which governs the size of the power supply for a pulsed magnet system, and the feasibility of conventional motor-alternator systems supplying energies up to perhaps 10° Joules per pulse is in some doubt. It is possible, however, to envisage a completely new type of power supply in which large superconducting coils are used to store and transfer the magnetic energy. The simplest version of this idea would consist of a pair of superconducting coils mounted on a

common shaft and rotating inside a larger coil, equivalent to a mechanically coupled motor and dynamo; if the parameters are chosen correctly, such a device could be used to transfer energy repetitively between a superconducting energy storage coil and a synchrotron magnet with negligible loss. Moreover, despite the size of the coils (in the region of 3 to 6 m diameter for 10° Joules), the cost of such a system is likely to be less than that of a conventional power supply.

A rather more straightforward and less speculative accelerator application would be the use of superconducting magnets in particle storage rings. In this technique, beams of particles from an accelerator are fed into two intersecting rings of d.c. magnets; the two beams of particles circulate continuously, and, when a sufficiently high density of particles has built up, an appreciable number of head-on collisions occur in the intersection regions, the effective energy in such collisions being very much higher than in the usual case of a simple beam hitting a stationary target. (For example, two colliding 30 GeV beams are equivalent to a single beam of energy 2,000 GeV.) The magnet rings are similar in type and size to that of a particle accelerator, but do not have the problems of pulsed operation, so that the use of superconductors will obviously be seriously considered for any large installations of this type built in the future

Finally, we consider what is perhaps a more urgent future problem—the construction of even larger bubble chambers to partner the new accelerators now planned. Diameters of 10 to 25 m have been mentioned for these hydrogen chambers. At this sort of size the surrounding magnet coils would have to be fabricated in situ, and this might involve the development of entirely new conductor configurations and constructional techniques. One obvious extension of existing technology would be to develop larger cross-section superconducting cables, carrying perhaps hundreds of thousands of amperes; a more attractive possibility, however, might be to deposit layers of superconductor on prefabricated surfaces of the required shape and mechanical strength by a process such as plasma spraying. This technique is already possible on a small scale and could be used in principle to form coils of indefinitely large size. Although it is not possible to foresee which of these, and many other possibilities, will eventually prove successful, it is evident that substantial advances in superconductor technology will be necessary before these very large magnets become economically realistic.

Recognition of Syntactic Structure by Computer

by P. BRATLEY H. DEWAR J. P. THORNE

A computer program has been designed to simulate the process by which humans recognize the syntactic structure of sentences.

Department of Computer Science and Department of English Language, University of Edinburgh

An essential part of the capacity to understand utterances lies in the ability to recognize syntactic structure. Over many centuries, grammarians have devised a special vocabulary for describing these structures. This vocabulary includes terms such as word, sentence, noun, verb,

subject and object. Unfortunately, grammar is usually taught in a way which obscures an interesting and important fact about grammatical analyses—that they are statements about what every native speaker knows about his language. It is therefore necessary to emphasize the point. Every

English speaker, irrespective of whether he has ever heard of, or understands the meaning of, terms such as noun and verb, possesses the information contained in statements such as the following: in the utterance The cat sat on the mat, cat is a word and catsa is not; the word the occurs twice; cat is the same class of word as mat and a different class from sat, the and on; the cat is a phrase but cat sat is not. A speaker could not understand the utterance unless he possessed this information.

It is important to notice that only some of this information-how much is disputable-is derived directly from what the speaker hears. For example, there is nothing in the pronunciation of cat which suggests the word shares characteristics with mat which it does not share with sat. Recognizing the syntactic structure of a sentence is not just a matter of hearing it. It is also a matter of knowing the syntactic structure of the language.

A grammar is a set of statements about what the native speaker knows about the structure of his language. The scientific study of grammars dates from the publication in 1957 of Chomsky's book Syntactic Structures¹. Chomsky, for the first time, laid down the formal conditions which a grammar must satisfy if it is to count as a reasonable description of the native speaker's knowledge of the structure of his language.

Chomsky shows that what is required is a set of effectively computable rules, which must be finite (because it is a model of knowledge "internalized" by a human being) but which is capable of generating an infinite number of sentences together with their analyses (because the number of well formed sentences in any natural language is infinite). Chomsky was also the first to set out clearly the empirical conditions which a grammar of a natural language must satisfy. The most important is that the grammar should generate all and only the well formed grammatical") sentences of the language. The conditions also include the requirement that in the case of an ambiguous sentence such as I dislike climbing plants, the grammar should reflect the ambiguity by assigning two analyses—that is to say, the grammar must contain two sets of rules for generating the sentence.

Chomsky also points out that, for many kinds of sentences, not all the syntactic information about them available to the native speaker relates to elements that he actually hears. There is, for example, the sentence The girl I liked left. Any English speaker hearing this sentence possesses the information contained in the statements that the girl I liked is the subject of the sentence and left is the predicate, and that the is a definite article, girl a noun, etc. This Chomsky calls information about the "surface structure" of the sentence. But any English speaker also knows that in this sentence, the girl is not only the subject of left but also the object of liked, even though, of course, the correct surface form of the sentence is The girl I liked left not The girl I liked the girl left. Because we derive this information from the sentence without making any reference to the context-as here where it is used merely as an examplethen it is clear that we derive this information not from the context (as is sometimes suggested) but from our perception of the structure of the sentence, even though, as we have seen, this part of the structure is not actually realized in the surface form of the sentence. The information forms part of what Chomsky terms the "deep of the sentence. If a grammar is to be a complete statement of the native speaker's knowledge of the syntactic structure of his language, it must assign both deep and surface structure analyses to all wellformed sentences of the language.

Many of the structural characteristics of natural languages are still not properly understood. But enough progress in developing models of the native speaker's knowledge of the syntactic structure of his language has been made in recent years to lead some linguists and psychologists to begin work on a further problem—the

problem of how human beings employ this knowledge in recognizing the syntactic structure of the utterances they Constructing a computer program of the kind described here to simulate the process is one approach to the problem. Because very little progress has so far been made in automatic speech perception, the program has been designed to work with an orthographic input, which means—because it is already divided into words—a partially analysed input. Even so, the problem of constructing an analyser which will provide both deep and surface structure information about arbitrary English sentences submitted to it in orthographic form is not trivial.

Most work on automatic syntactic analysis has been undertaken in the context of information retrieval, translation and other text-processing systems and has not aimed at simulating human behaviour. The chief differences between the analysers used in these systems (for example, the Harvard Predictive Analyser2, the MITRE Analyser³ and the FAP String Analysis Program4) and the analyser developed at Edinburgh5 are attributable to the fact that a syntactic analyser which is intended to model the way in which human beings recognize the syntactic structure of sentences must satisfy certain a priori conditions.

First, such an analyser must not be dependent on looking up every word of an input sentence in a dictionary. Other automatic parsers of English (or Russian and other languages) operate on the assumption that they will eventually incorporate a dictionary containing every word in the English (Russian, and so on) language, listing the parts of speech to which each word can be assigned. It seems unlikely that a speaker of the language needs to internalize and employ a dictionary of this kind in order to be able to recognize syntactic structure. On the one hand, everybody can recognize the syntactic structure of sentences which contain words we have never heard before (He has gone to shoot a grison, He is going to disple his mother-in-law). On the other hand, the knowledge that a word such as iron, say, may be a noun, an adjective or a verb is of no help in deciding its role on any particular occasion (He ruled with an iron hand, Strike while the iron is hot, I will iron your shirt tomorrow). It is because we are able to recognize the structure of these sentences that we know that iron is an adjective in the first example, a noun in the second, and so on.

This is not true of all words. Some, such as pronouns, conjunctions and prepositions, have fixed syntactic functions, and play an essential part in the recognition of sentence structure. Syntactic information is also provided by certain suffixes such as -s, -ed and -ing. Our program is designed to require access to a dictionary containing information only about those words with fixed syntactic functions (the closed-class words) and about suffixes of the type already mentioned. This dictionary is very short, approximately a thousand words. Nevertheless, with this dictionary alone, infinitely many English sentences can be analysed.

The second constraint our program must satisfy is that it must process each sentence in a single left-to-right pass, analysing each part of the sentence once and once only. Very many sentences are syntactically ambiguous. Nearly all sentences contain elements which, taken in isolation, are ambiguous. In view of the efficiency with which human beings recognize the syntactic structure of utterances, it seems reasonable to assume that in listening to utterances all possible analyses are usually considered simultaneously. The program is therefore designed so that, if an input sentence is ambiguous, the program will work on all the possible analyses simultaneously. In other words, the program does not follow through one analysis and then backtrack to see if others are possible. The progress of the analysis procedure is represented by a continuously growing data structure. When the end of the sentence is reached, each possible analysis is to be found represented as a complete path through this structure.

It seems equally reasonable to require that, if all ambiguous items are treated simultaneously, elements of a sentence which are not ambiguous should not be analysed more than once. For example, in the sentence He rolled up the bright red carpet, the phrase the bright red carpet is either the object of the phrasal verb roll up, or else the object of the preposition up. The analysis of the bright red carpet as a noun phrase is, however, the same for both interpretations. In a case such as this, the program will analyse the noun phrase once only and the structure representing this analysis will become part of two paths, representing the two possible analyses of the whole sentence.

Third, it seems necessary that the program should work in a predictive fashion. There is a good deal of evidence to suggest that the efficiency with which human beings recognize the syntactic structure of sentences is to some extent a result of their ability, having heard part of a sentence, to predict the structure of the remainder. It seems probable that having heard, say, the subject of a sentence, people then predict in some sense the occurrence of a verb to go with that subject. In the two examples He ruled with an iron hand and I will iron your shirt tomorrow, it is obvious that the kinds of words which can follow He ruled with an ... and I will ... are different. Roughly speaking, in the first case we are predicting a noun or an adjective, while in the second case we are

ture grammar1; the base grammar embodied in the analyser is a somewhat simpler type—a regular or finitestate grammar6—for which it is possible to describe the transformational rules more conveniently and economically. In outline, the base grammar specifies sequences of category-names. An example of such a sequence is PRONOUN VERB PRONOUN ADVERB, which would be instantiated by sentences like She visited him yesterday. It is possible to substitute for certain category-names not simply individual words but transforms which are themselves (modified) realizations of base strings. Thus He asked who admired Descartes is a possible realization of the string PRONOUN VERB INDIRECT-QUESTION, where the part who admired Descartes, which is substituted for INDIRECT-QUESTION, is derived from a realization of the string PRONOUN VERB PROPER-NAME. Associated with each element in a string there is also a syntactic relation marker (SRM) which describes tho syntactic role of the element in the overall structure of the string.

The output produced by the analyser reflects the form of the grammar. Each complete analysis of an input sentence is displayed in a series of numbered levels, the level structure corresponding to the transformational structure of the sentence. Within each segment of a level, the parsing of the individual units is indicated by the attachment of SRMs either to individual words or to the names of transforms. Thus for the two sentences quoted, the output would be

```
      1
      SE: STAT
      2
      SU: she
      AV: visited
      OB: him
      MO: yesterday
      2

      1
      SE: STAT
      1
      SU: he
      AV: asked
      OB: INDQ
      2

      3
      SU: who
      AV: admired
      OB: Descartes
      3
```

(See next page for a list of the abbreviations used)

predicting a verb. After the next word of the sentence, we can check that it fulfils at least one of our predictions and, on the basis of the predictions satisfied and our knowledge of the language, new predictions can be made. Accordingly, the operation of the analysis program is a process of making and checking predictions about the syntactic structure of a sentence in which the predictions made at any stage are governed by the grammar which is incorporated in the program.

This grammar is a transformational grammar. A transformational grammar consists of a base component and a transformational component. The base component specifies a set of strings which correspond roughly to the

Special conventions are used to indicate the analysis of sentences involving inversion and co-ordination. Inversion is exemplified by such interrogative and relative constructions as:

Has he informed the police? (inversion of auxiliary) The apples which they bought were rotten

(inversions of object of bought)

Which book do you want?

(inversion of both auxiliary and object). In the printout the inverted unit is labelled with a dummy SRM (OO) and the position from which the unit is inverted is marked by a genuine SRM attached to an asterisk. Thus for the sentences quoted above the output would be

```

An analyser which simulates the process by which human beings recognize the syntactic structure of sentences in certain obvious ways is interesting only in as far as it serves as a source of hypotheses about aspects of this process which are not obvious. For example, it could be that the sequence of operations in the program will throw some light on the structure of the human performance. One specific line of research is an investigation of the extent to which the processing time of the analyser can provide a measure of the complexity presented by sentences to the human hearer. Another is to study in which ways the structure of the program has to be changed in order to produce output which would reflect features of various language disorders. A major problem

in all these cases is to distinguish those features of a model which are significant from those which are merely a consequence of the fact that the model is a computer program.

Angular Measurements of the Structure of 3C 446 and Other Quasars with High Red-shifts

by

G. K. MILEY B. J. RICKETT

Nuffield Radio Astronomy Laboratories, University of Manchester, Jodrell Bank, Cheshire

H. GENT

Royal Radar Establishment, Malvern

Measurements of the radio source 3C 446 show that it is elongated in the east—west direction and may well be a double source. 3C 9 also seems to be a double source, and PKS 1116+12 and 4C 31:38 have angular dimensions <0·1 and <0·2 sec arc, respectively, in at least one direction.

LITTLE is known about the angular dimensions of quasars with large red-shifts. Although there are now more than twenty quasars with red-shifts greater than 1.4, only the structures of 3C 270·1, 3C 298 and AO 0952+17 have been published¹⁻³. Three others, 3C 191, 3C 454 and PKS 0106+01, showed high fringe visibilities when observed with interferometers of baseline sixteen or twenty thousand wavelengths^{1,4}, while 3C 446 is known to have an angular dimension less than 0.3 sec are at 67 cm wavelength⁵. Finally, PKS 1148-00 and 3C 446 both lie in the category of radio sources with an angular dimension smaller than about 0.05 sec arc at 11 cm listed by Palmer et al.6. Their communication gave a preliminary account of observations of forty-six radio sources with an interferometer between Jodrell Bank and the Royal Radar Establishment, Malvern, with a baseline 127 km long: the wavelengths of observation were 21 cm, 11 cm and 6 cm. We present here a full analysis of the 21 cm measurements on the quasar 3C 446, showing that it is significantly resolved at this wavelength. We also give the results of further observations at 18 cm and 73.5 cm on three additional quasars with high red-shifts.

3C 446

For interferometric measurements, the radio source 3C 446 was observed continuously at 21 cm for 5 h on September 2, 1966, and the resultant variation of fringe visibility with hour angle is shown in Fig. 1. In calculating the visibilities the 21 cm flux density was assumed to be 5.9×10^{-26} Wm⁻² c/s⁻¹, this value being taken from the Parkes survey⁷ and the work of Conway, Kellermann and Long⁸. The method of analysis and the calibration pro-

cedure will be discussed in detail elsewhere. The error bars include errors caused by calibration and uncertainty in the flux, but no allowance has been made for possible variability.

The dependence of the effective resolution vector on hour angle for 3C 446 at both 21 cm and 11 cm wavelengths is shown in Fig. 2. Because of the low declination of this source the magnitude of the north-south resolution does not change greatly as the source moves through the sky. This increases the difficulty of fitting a model brightness distribution to the visibility curve. Although a fit can be obtained for a single elliptical Gaussian model, other quasars the structure of which has been resolved consist characteristically of two separated regions of

radio emission. The 21 cm results were therefore fitted with a double model having two circular Gaussian components of equal diameters but unequal fluxes. The computed best fit (least mean square deviation between model and observed results) was obtained with components of half power width 0.15 ± 0.04 sec arc, separated by 0.37 ± 0.15 sec arc in position angle $83^{\circ} \pm 16^{\circ}$ with flux ratio 0.2 ± 0.1 . The visibility curve of this model is shown by the broken line in Fig. 1. A double model with a similar separation and position angle in which the weaker component is a point source fits the data equally well.

 $3\bar{C}$ 446 was also observed for a short time at a wavelength of 11 cm when its visibility increased from 0.70 ± 0.04 to 0.81 ± 0.04 between hour angles 21.5 and 23.5 (private communication from W. Donaldson). It is difficult to reconcile the behaviour of the visibility functions at 21 cm and 11 cm with a frequency-independent model of the source. It seems probable that $3\bar{C}$ 446 is double, that the spectra of the two components differ and that the flux inequality is greater at 11 cm. A less probable explanation of the results is that $3\bar{C}$ 446 has a single elongated component the size of which increases with wavelength.

Some further evidence on the angular structure of 3C 446 comes from scintillation measurements made with the Mark I telescope at Jodrell Bank during February and March 1967. During this period 3C 446 approached within 4° of the Sun. Strong scintillations were observed at a wavelength of 73.5 cm out to solar elongations of 25°. The intensity from the source was sampled at a rate of twenty-five samples per sec, and the auto-correlation function was calculated during the observations by an

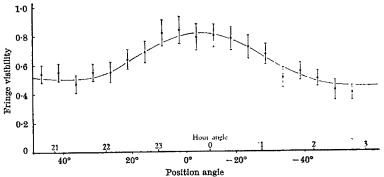

Fig. 1. Variation of fringe visibility with hour angle for 3C 446 at 21 cm. The line shows the best fitting double Gaussian model.

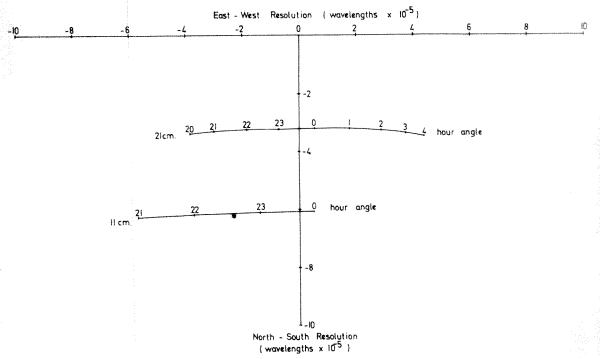

Fig. 2. Variation of the resolution on 3C 446 with hour angle, using Jodrell-Malvern baseline.

on-line computer. The rate of scintillation is measured by the width of this auto-correlation function, and the method of analysis is similar to that used by Cohen et al.⁹.

An extended source produces a reduced scintillation index and, in addition, the measured auto-correlation function is broadened by an amount depending on the angle between the solar wind and the source axis. An elliptical Gaussian brightness distribution has been assumed for the source, and the measured auto-correlation function was compared with that predicted using the two dimensional diffraction theory of Little and Hewish¹⁰. The predicted auto-correlation function is $\exp(-t^2/\tau^2)$, where the time scale of the scintillations is given by

$$\tau^2 = \{a^2 + 2L^2 (\theta_0^2 \cos^2 \alpha + \varphi_0^2 \sin^2 \alpha)\}/v^2$$

where a is the scale of the point source diffraction pattern which is assumed isotropic and moving radially out from the Sun at a velocity v; L (= 1 astronomical unit) is the distance to the diffracting medium; the 1/e radii of the source are θ_0 and ϕ_0 ; and α is the angle between the solar wind and the major axis. Measurements were made of the scintillation index and time scale, \u03c4, as the Sun moved past the source. The properties of the diffracting medium are functions of solar elongation and may vary with time. For this preliminary analysis, however, a simplifying assumption has been made that the scale of the pattern, a, and velocity, v, are functions of elongation only. On both February 17 and March 6 the solar elongation was 10° , but the angle, α , differed by 60° . The respective values of scintillation index were 0.4 and 0.3 which agree with the assumption of no large changes in properties of the solar wind, and are somewhat smaller than might be expected for a point source. The values of τ for these

dates were measured as 0.4 sec and 0.8 sec. Using the expression for τ , the limits for the half power widths of an elliptical Gaussian model are $\gtrsim 0.34$ sec are by $\lesssim 0.19$ sec arc, with the major axis at a position angle of $94^{\circ}\pm30^{\circ}$. These preliminary results also agree well with the double model fitted to the interferometric data at 21 cm wavelength.

Although the results from both techniques leave considerable latitude in possible models of source structure, there is little doubt that 3C 446 is elongated in the east—west direction, in which it has an angular extent of about 0·3 sec arc.

PKS 1116+12 and 4C 31.38

In January 1967, after a series of galactic OH line observations¹¹, a few continuum measurements of quasars were made at 18 cm. Fringes were obtained for about 1 h from each of the quasars PKS 1116+12 and 4C 31-38, both of which have high red-shifts. Using 3C 287 for calibration, the fringe visibilities were 1.3 ± 0.3 and 0.9 ± 0.3 , indicating that these quasars have angular dimensions <0.1 sec arc and <0.2 sec arc, respectively, in at least one direction, as shown in Table 1.

3C 9

In September 1967 the quasar 3C 9 at a wavelength of 73·5 cm was observed with the Mark I telescope at Jodrell Bank and the new Mark III telescope which is situated near Nantwich. The length of this baseline was 31,000 wavelengths. A complete analysis of these observations together with details of the instrument will be given later, but 3C 9 seems to be a double radio source with a separation of about 8 sec arc, as shown in Table 1.

^{*} Provisional interpretation. † Assuming z purely cosmological and $q_0 = \sigma_0 = 1$.

Scintillation measurements were also made on this source at the same wavelength giving a scintillation index of < 0.1, which indicates that it has little structure smaller than 0.3 sec arc.

Information about the linear dimensions of the sources is also given in Table 1 for the case where the red-shifts are purely cosmological in origin. At these large red-shifts, the linear sizes are greatly influenced by the geometry of the Universe, and a cosmological model in which $q_0 =$ $\sigma_0 = 1$ has been used (where q_0 is the acceleration factor and σ_0 the density parameter). Factors for conversion to other models are given by McVittie¹². The difference between the dimensions of 3C 9 and PKS 1116+12 (both of which have approximately the same red-shifts) is nearly two orders of magnitude, which indicates that even at these large red-shifts the intrinsic dispersion in the dimensions of quasars would mask any cosmological effects.

For 3C 446 an angular dimension of 0.3 sec are would correspond to a linear dimension of about 103 parsec if the red-shift is cosmological, or about 10 parsec if 3C 446 is situated at a distance of 10 Mparsec. These values may be compared with the upper limits of 10-3 parsec on the size of the regions emitting the optical continuum radiation, calculated from the time scale of the large variations in the light received from 3C 446 during 1966 (ref. 13).

Apart from 3C 9, the quasars in Table 1 all have comparatively flat radio spectra as well as small angular dimensions, both properties characteristic of variable radio sources. 3C 446 is known to be variable at 1.96 cm observed wavelength¹⁴ (0.82 cm emitted wavelength); it would prove valuable to observe PKS 1116+12, 4C 31-38 and also PKS 1148-00 for possible variability. The magnitude of variations in the radio output of quasars has been shown to be greater at short wavelengths 15, but because of their high red-shifts it would be valuable to monitor the fluxes of these quasars at comparatively long observing wavelengths.

Molecular Hydrogen in Pre-galactic Gas Clouds

WILLIAM C. SASLAW DAVID ZIPOY

Department of Applied Mathematics and Theoretical Physics, University of Cambridge

During the collapse of pre-galactic gas clouds through a density of about 10^4 particles/cm³, hydrogen molecules are produced and dominate the subsequent cooling.

In a plausible picture of galaxy formation, proto-galaxies are produced by the gravitational clustering of many gas clouds^{1,2}. Various origins for these clouds have been discussed by Lifshitz³, Bonnor⁴, Saslaw⁵ and Harrison⁶ among others. In this article, the important, and probably dominant, part that molecular hydrogen plays in the early evolution of large clouds is first investigated, and then the possibility of detecting the radiation they produce is discussed.

The era examined occurs in the conventional big-bang cosmology after matter and radiation have decoupled and before star formation has begun. During this period, $z\lesssim 1,000$, the recombination time scale for hydrogen exceeds the Hubble time, and about one hydrogen atom in 10⁵ remains ionized⁷. Then, by an unknown process, gravitationally bound condensations are assumed to establish themselves. At first, they will expand rather more slowly than the rest of the universe. Later, at a time determined by the ratio of their mass to the Jeans mass, they will contract. For the detailed cosmological model, that of Einstein and de Sitter is assumed, although this is not critical.

Hitherto, H₂ has not been considered a component of the pre-galactic medium. This was because the time scales for appreciable amounts to form in three-body reactions or in radiative association are always greater than the Hubble age (for example, ref. 8), and there are no grains to speed the reactions. Any H₂ formed in the uniform background is dissociated by the radiation, until the density is too low to produce it. We find, however, that later, in the condensations, charge transfer reactions produce enough H2 to radiate most of the thermal energy of contraction. General references to the chemistry of charge transfer reactions may be found in ref. 9. Here we consider only those relevant to H2 (P. Solomon, private communication)

$$e^- + H^+ \rightarrow H$$
 (1)

$$\mathbf{H} + \mathbf{H}^+ \rightarrow \mathbf{H}_2^+ + hv$$
 (2)
(0.7 eV at 2,000° K)

$$\mathbf{H}_{2}^{+} + \mathbf{H} \rightarrow \mathbf{H}_{2} + \mathbf{H}^{+} \tag{3}$$

$$H_2 + H \rightarrow 3H$$
 (4)

If helium is present, small amounts of HeH+ and related compounds may form. But these, as well as H-, are not likely to be important. Evidently reactions (2) and (3) form a cycle and one proton may produce many hydrogen molecules. This cycle competes with hydrogen recombination and H2 dissociation, and it is necessary to turn to a detailed computation of their rivalry.

In a contracting cloud model, we begin with a spherical cloud of pure hydrogen at its moment of maximum expansion. We assume that its density is comparable with the average density of the universe at that time (an assumption which does not affect the important results seriously) and that its mass is sufficiently greater than the Jeans mass to enable free fall to prevail. The equations which determine the chemical composition are

$$\dot{N}_{+} = \frac{1}{V} N_{0} N_{2+} < \sigma v >_{2} - \frac{(N_{+} + N_{2+}) N_{+}}{V} < \sigma v >_{0} - \frac{N_{+} N_{0}}{V} < \sigma v >_{2+}$$
 (5)

$$\dot{N}_{2+} = \frac{1}{V} N_0 N_+ \langle \sigma v \rangle_{2+} - \frac{1}{V} N_0 N_{2+} \langle \sigma v \rangle_{2}$$
 (6)

$$\dot{N}_2 = \frac{1}{V} N_{2+} N_0 \langle \sigma v \rangle_2 - \frac{1}{V} N_2 N_0 \langle \sigma v \rangle_{\text{dissoc}}$$
 (7)

$$N_0 + N_+ + 2N_{2+} + 2N_2 = N \tag{8}$$

where N_+ , N_2^+ , N_2 , N_0 are the total numbers of particles of \mathbf{H}^+ , \mathbf{H}_2^+ , \mathbf{H}_2 , \mathbf{H} in a volume V, N is the total baryon number in V and the $\langle \sigma v \rangle$ s are rate coefficients for reactions (1) to (4). We also need the equations for energy conservation and the velocity of free fall

$$\left(\frac{3}{2}NkT\right)^{\bullet} = -P\dot{V} - \Lambda V = -NkT\frac{\dot{V}}{V} - \Lambda V \qquad (9)$$

$$(\dot{L})^2 = 2 GM \left(\frac{1}{L} - \frac{1}{L_0}\right) \tag{10}$$

where T is the temperature, k is the Boltzmann constant, P is the pressure and Λ is the radiation rate in erg cm⁻³ sec⁻¹. The total mass, initial radius and the time dependent radius of the sphere are M, L_0 and L, respectively. The pressure term in equation (9) indicates that the radiated energy is essentially the P d V work done by the collapsing cloud.

Three approximations promote simplicity with little loss of accuracy. First, although og is not accurately known, it most probably has a value of about 10-15 cm² which is typical of charge exchange reactions above threshold, and is therefore much greater than σ_{2+} . Thus an H; ion is converted to H, as soon as it is formed and the H₂ concentration never becomes large. As a result of this large cross-section and also the low electron concentration, dissociative recombination of H₂ is negligible compared with reaction (3). Second, dissociation of H₂ is negligible below about 6,000° K. We therefore omit it because—as will be found—the temperature does not rise sufficiently high for dissociation. Finally, nearly all particles will be in the form of hydrogen atoms. Thus we have $N_+ + N_{2+} \approx N_+$; $N_0 \approx N$; $N_{z+} + N_2 \approx N_2$ (after the short initial H_2^+ production). If we combine equations (5) and (6), (6) and (7) and change the notation, we have

$$\frac{\mathrm{d}m}{\mathrm{d}y} = -\frac{A - m^2}{\sqrt{g} \sqrt{y - 1}} \tag{11}$$

$$\frac{\mathrm{d}n}{\mathrm{d}y} = B \ m \ g^2 \frac{y^5}{\sqrt{y-1}} \tag{12}$$

$$\frac{\mathrm{d}g}{\mathrm{d}y} = -\frac{2}{3} \frac{t_f}{\mu_0 k T_0} \frac{\Lambda}{y^7 \sqrt{y-1}} \tag{13}$$

in which we define $m=(N_++N_{2+})/N\approx N_+/N$, $n=(N_{2+}+N_2)/N\approx N_2/N$, $T=T_0gy^2$, $y=L_0/L$, $A=\mu_0t_f<\sigma v>_0^0$, $B=\mu_0t_f<\sigma v>_0^2$, and $t_f=(8\pi Gm_p\mu_0/3)^{-\frac{1}{2}}=$ free fall time. The initial total number density and temperature at the start of free fall are μ_0 and T_0 , respectively, and $<\sigma v>^0$ denotes a rate constant at $T=T_0$. The rate constants are

$$\begin{aligned} &<\sigma v>_0\approx 6\cdot 3\times 10^{-11}~T^{-\frac{1}{2}}~{\rm cm^3/sec}~({\rm ref.}~10) \\ &<\sigma v>_{2+}\approx 5\times 10^{-24}~T^2~{\rm cm^3/sec}~({\rm ref.}~11) \end{aligned}$$

where T is in °K. Their temperature dependence has been inserted into equations (11) and (12). It is more convenient to use y than t for the independent variable. The function g is just the ratio of the actual temperature to the temperature the cloud would have had if its collapse were adiabatic.

Takayanagi and Nishimura¹² have calculated the radiation function Λ and we fit it to an approximate formula

$$\Lambda = 2.5 \times 10^{-31} T^{2.4} \mu_{H^{2/3}} \mu_{2} \text{ erg cm}^{-3} \text{ sec}^{-1}$$

where μ_H and μ_2 are the number of densities of H and H_s. This fit is accurate to about a factor of two in the range $500^{\circ} < T < 5,000^{\circ}$, $10 < \mu_H < 10^4$. Outside this range, it overestimates the cooling. Equation (13) now becomes

$$\frac{\mathrm{d}g}{\mathrm{d}y} = -1.67 \times 10^{-31} \frac{g^{2.4}y^{2.8}}{k\sqrt{y-1}} \mu^{2/3} t_f T^{1,4} n \tag{14}$$

It should be noted that these equations do not depend on the size of the cloud as long as it is large enough for the free fall approximation to be valid. In effect the only free parameters are the average matter density in the universe now, the initial number fraction of H⁺ and the red-shift when the collapse begins.

We have numerically integrated equations (11), (12) and (14) using the initial conditions y=1, n=0, g=1. The values of the parameters are $\rho_{\text{now}} = 2 \times 10^{-29}$ g/cm³, $m_{\text{initial}} = 10^{-5}$, $z_0 = 5$; z_0 is the value of red-shift when the collapse starts, $1 + z_0 = (t_{\text{now}}/t_0)^{2/3}$ where t_{now} is the present age of universe and t_0 is the age when collapse starts. Given z_0 , values of μ_0 and T_0 are found from the formulae for the background gas which expands adiabatically and conserves baryons: $T_0 = T_{\text{now}}(1 + z_0)^2$, $\mu_0 = \mu_{\text{now}}(1 + z_0)^3$ with $T_{\text{now}} = 3 \times 10^{-3}$ °K.

The results are shown in Fig. 1. To understand them qualitatively, return to equation (9) and integrate it to find

$$E_{(t)} \equiv \int_{t_0}^{t} \Lambda V dt = \frac{3}{2} Nk \left[T_{(t)} \log \frac{1}{g} + T_0 \int_{u_t}^{\mu(t)} \frac{dT}{d\mu_{\text{tot}}} \log g \ d\mu_{\text{tot}} \right] \tag{15}$$

where E(t) is the total energy emitted up to time t. We see that this depends explicitly only on T(t) and $\mu_{tot}(t)$, the total density at time t. A numerical computation for $z_0 = 20$ (that is, higher initial density) shows that T does not depend on the starting time, but only on μ_{tot} . This is reasonable because the radiation is essentially a consequence of the work done on the gas and this is appreciable only after contraction to a fairly high density. Similarly, we conclude that the energy radiated is essentially independent of the initial concentration of H+. For suppose the initial H+ concentration were less, then the cloud would contract more before forming H2, and its maximum temperature would be higher. Then the cloud once again would cool and, after the temperature had dropped to a few hundred degrees, the net work would be about the same as before. This argument breaks down,

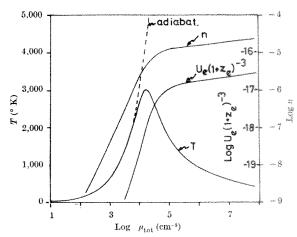

Fig. 1. The temperature, T, fraction of hydrogen, n, and the "invariant" energy density, $U_1(1+Z_c)^{-3}$, are plotted as a function of the instantaneous total density, μ_{-1} , of the collapsing cloud. The dashed extension of T gives the temperature if the cloud does not radiate. The initial conditions are $z_0=5$, $m_0=10^{-5}$, ρ_{210} , ν_{110} , $\nu_{110}=\nu_{110}$, $\nu_{110}=\nu_{110}=\nu_{110}$, as similar plot with $z_0=20$ differs from these curves by less than 10 per cent.

of course, when there is so little H+ that the cloud heats adiabatically and ionizes before appreciable H₂ can be

Now that we have found that H2 prevents the cloud from heating, we may ask if its radiation can be detected. From the total energy radiated by a single cloud, we want to find the average radiation flux striking a detector now. First, the average radiation energy density produced by these clouds is computed, assuming that all the matter of the universe is in clouds and collapses instantaneously. Then this is multiplied by the fraction of matter that actually collapses between t and t+dt. Then dt can be converted to a spread in wavelength by using the cosmological Doppler formula, and finally the result is multiplied by the speed of light to find a flux density between λ and $\lambda + d\lambda$.

All the matter in the universe, if it emits at a red-shift of z_e , produces an energy density

$$U_e = \frac{\mathcal{H}E}{V_u} (1 + z_e)^3 \tag{16}$$

where \mathcal{M} is the total number of clouds, V_n is the volume of the universe now and E is given by equation (15). Because most of the radiation comes out in a short burst (about 1 per cent of free fall time), E(t) is approximately constant after the density becomes greater than about 10⁵ cm⁻³, well past the peak of emission (see Fig. 1). It can be seen from equations (15) and (16) that $U_e(1+$ $(z_e)^{-3}$ is independent of (z_e) and is proportional to the present number density of particles. The value of this "constant", as determined from equation (15) and the results in Fig. 1, is

$$\frac{\mathcal{H}E}{V_B} \approx 1.5 \times 10^{-17} \text{ erg/cm}^3$$
 (17)

The flux between λ and $\lambda + d\lambda$ is then given by

$$F_{n\lambda} d\lambda_n = \frac{c}{4\pi} U_e (1 + z_e)^{-4} G_{(te)} dt_e \text{ erg cm}^{-2} \text{ sec}^{-1} \text{ ster}^{-1}$$
 (18)

where λ_n is the wavelength of interest now, $G_{(t_e)}dt_e$ is the fraction of clouds which emit between t_e and $t_e + dt_e$, and the factor $(1+z_e)^{-4}$ converts from emitted to present energy density. Next dt_e is converted to $d\lambda_n$ by the cosmological Doppler formula

$$\lambda_n = (1 + z_e)\lambda_e = \lambda_e (t_n/t_e)^{2/3}$$
(19)

$$|dt_e| = 1.5t_n \lambda_n^{-1} (1 + z_e)^{-1.5} d\lambda_n$$
 (20)

Finally, from equations (16), (17), (18) and (20) we obtain $\lambda_n F_{n\lambda} = 5 \times 10^{-8} t_n G_{(t_e)}(t_e/t_n)^{5/3} \text{ erg cm}^{-2} \text{ sec}^{-1} \text{ ster}^{-1}$ (21)

The radiation is emitted by collisionally excited rotational lines of H₂. At the temperatures given in Fig. 1, there are three strong lines: the $l=8\rightarrow6$, $6\rightarrow4$, and $4\rightarrow2$ transition lines with relative intensities of approximately 1:1:0.5. Their rest wavelengths are 4.4, 5.6 and 7.6μ , respectively. Actually there are also lines between these which correspond to the rotational transitions between odd l values for hydrogen in the ortho spin state; although Takayanagi and Nishimura considered only parahydrogen, including orthohydrogen, would not change the cooling rates or total radiation appreciably, but would distribute the energy over more lines. In our case, however, the cloud emission function $G_{(t_e)}$ would smear the lines into a con-Thus the relevant wavelength is a weighted average of the emitted lines which is about 5µ in the rest frame.

As a favourable numerical example, suppose that the clouds radiated when the age of the universe was between 1 and 2×10^9 years. Then using $G_{(t_e)} \approx 10^{-9} \text{ yr}^{-1}$ and $t_e \approx 1.5 \times 10^9 \text{ yr}$, $t_n = 10^{10} \text{ yr}$, $\rho_n = 2 \times 10^{-29} \text{ g/cm}^3$, we obtain $\lambda_n F_{n\lambda} = 2 \times 10^{-8} \text{ erg cm}^{-2} \text{ sec}^{-1} \text{ ster}^{-1}$. The peak is near $\lambda_n \approx 20\mu$ and has a full width of about 10μ . Total intensity is proportional to the baryon number of the universe. In

this calculation, the most uncertain quantity is G. Not enough is known about the physics of self gravitating gas to rule out possible collective effects which may increase G and $F_{n\lambda}$ substantially. It should be mentioned that there is some evidence, from the radio source counts¹³, for an appreciable decrease of radiation emission for $z \gtrsim 4$ $(t \approx 10^{\frac{1}{9}} \text{ yr})$. This could indicate that our value of G may not be overly optimistic.

Because of atmospheric absorption, there are no detailed observations of the 15-30µ background. Partridge and Peebles^{14,15} have estimated approximate upper limits to the chief background contributions in this band, from extragalactic Ne+ emission, metallic interstellar grains, and galactic free-free emission, to be about 2×10^{-6} , $4 \times$ 10^{-7} , and 2×10^{-7} erg cm⁻² sec⁻¹ ster⁻¹, respectively. Integrated starlight from the galaxy, perpendicular to the plane, may also be about 10⁻⁷. In addition, the integrated infrared radiation from distant galaxies may be comparable. These numbers are about a factor of ten to a hundred times larger than our reasonably optimistic estimate for H2 emission. But because they are so uncertain, the H₂ emission we have discussed could be an important contributor. If so, it could be distinguished from galactic radiation by its lack of angular dependence, and from Ne+ by its smoother spectrum. The shape of the H_2 spectrum is a direct measure of $G_{(t_0)}$, the cloud emission function, and we would not expect this to rise monotonically with time and then abruptly stop at some epoch, as would be required for the H2 spectrum to mock that of Ne+.

In conclusion, we find that if the clouds quickly contract to a density above about 104 particles/cm3, they will produce enough H₂ to cool very rapidly. Under optimum conditions it may be possible to detect this radiation. The further collapse, if spherical and not stopped by rotation or magnetic fields, continues until the optical depth becomes large. This does not occur until densities considerably greater than those necessary to produce H_z are reached. A massive cloud then continues to collapse until the H₂ dissociates and the hydrogen atoms ionize. Thus it faces two more cooling instabilities, both of which would promote fragmentation and further collapse. A small opaque cloud contracts gradually. In any case, at the high densities reached we would expect stars to form. This could produce enough ultraviolet radiation to ionize the remaining gas and expel it from the cloud. Although the resulting object probably resembles a globular cluster, we would not wish to maintain that this describes their mode of formation without further detailed

We are grateful to Dr P. Solomon for several helpful discussions about molecular hydrogen. We also thank Dr E. A. Spiegel and Mr M. J. Rees for their comments on the manuscript. One of us (W. C. S.) thanks the US National Science Foundation for a pre-doctoral fellowship during which this work was done. D. Z. was on sabbatical leave from the Department of Physics and Astronomy, University of Maryland, and thanks NATO for their fellowship support and also the Department of Applied Mathematics and Theoretical Physics of the University of Cambridge for their hospitality during the past year.

Theory of Universal Primary Interactions

by
E. C. G. SUDARSHAN
Syracuse University,
New York

This theory originates from observations that the theory of particle interactions becomes much simpler and more capable of correlating apparently unrelated phenomena if it is postulated that electromagnetism and weak interactions are not primary properties of the nucleons but are acquired by virtue of their interaction with vector and axial vector fields.

TEN years ago, Marshak and I analysed the then existing experimental data on weak interactions and concluded that all the experiments could not be consistently interpreted in terms of a general theoretical scheme¹. We singled out four crucial experiments which should be remeasured with different results if a satisfactory theory of weak interactions was to be developed. We also showed that the only possible universal theory would be a vectoraxial vector interaction. This was satisfying because the principle of chirality invariance for the interaction, already valid for electromagnetism, unambiguously led to this interaction. Almost immediately Feynman and Gell-Mann² developed the same theoretical scheme and re-introduced the notion of a conserved vector current3 to show why the vector coupling constant was not re-normalized. The chirality invariant theory, which we formulated a decade ago1,2, has been accepted as the theory of universal Fermi interaction. Even the small departure of the ratio of the vector and axial vector coupling constants from unity by a factor of approximately $\sqrt{(25/18)}$ can be computed on the basis of the original formulation of the theory4.

Several new experimental developments, however, make it desirable to re-examine the theoretical basis for the universal four-fermion interaction. Within the realm of weak interactions, it has been found that the leptonic decays of kaons and hyperons are slower, by a factor of about ten, than the predictions of the universal fourfermion interaction extended to strange particles. There is now unmistakable evidence for a small violation of CP invariance in weak interactions leading to the neutral long lived kaon. Among strong interactions, the existence of a whole collection of vector mesons has been experi-mentally established. These mesons are strongly coupled to baryons and their contribution to low energy pionnucleon scattering and the electromagnetic properties of the nucleons make them essential to an understanding of particle interactions. In fact, soon after the first vector meson resonances were experimentally identified, following a method suggested by us, Sakurai pointed out the qualitative explanation of some features of strong interactions based on the hypothesis of a universal vector meson coupling to hadrons (for discussion see refs. 7-10). Evidence has been accumulating for the validity of such a universal coupling. Finally, there has been some evidence for axial vector meson resonances, although they cannot yet be considered experimentally established.

Interaction Types and Families of Particles

In the present theory, I distinguish four families of particles and their associated fields. These four families have their characteristic interaction properties and are shown in Table 1.

The pseudoscalar and pseudovector mesons are both quanta of the same axial vector field, and may be written

$$A_{\lambda} = B_{\lambda} + \xi \frac{1}{m\pi} \partial_{\lambda} \varphi_{\pi}; \ \partial^{\lambda} B_{\lambda} = 0$$
 (1)

where φ_{π} is the pion field and B_{l} is the transverse part associated with the pseudovector particles. As a consequence

$$\partial^{\lambda} A_{\lambda} = \xi \cdot \frac{1}{m_{\pi}} \cdot \Box^{2} \varphi_{\pi} = -\xi \cdot m_{\pi} \cdot \varphi_{\pi}$$
 (2)

where the second member is strictly valid only when the pion is on the "mass-shell". On the other hand, the vector field has only a vector particle because it is required that

$$\partial^{\lambda} V_{\lambda} = 0 \tag{3}$$

The nucleon field is denoted by N and the electromagnetic field by a_{λ} . It is now possible to formulate the fundamental primary interactions. For simplicity, in the first instance, the strange particles are ignored.

(i) Electromagnetism

The electrons and muons are coupled to the Maxwell field, a_{λ} , according to the usual form

$$-e \left(\overline{\mu}\gamma_{\lambda} \mu + \overline{e} \gamma_{\lambda} e\right) a^{\lambda} \tag{4}$$

The nucleons are not directly coupled to the Maxwell field, but the neutral vector fields ρ and ω are coupled according to

$$- (e/g) (m_{\varrho}^2 \cdot \rho_{\lambda} + m_{\omega}^2 \cdot \omega_{\lambda})$$
 (5)

where g is a strong coupling constant, the value of which is specified later.

$(ii) \ Strong \ Interactions$

The leptons do not have any strong interactions. The strong interactions are completely specified by the Yukawa coupling

$$\frac{1}{2} g \overline{N} \left\{ \gamma^{\lambda} \mathbf{\tau} \cdot \mathbf{\rho}_{\lambda} + (g'/g) \sigma^{\lambda \nu} \stackrel{1}{=} \mathbf{\tau} \cdot \mathbf{\rho}_{\lambda \nu} \right.$$

$$+ (g_{0}/g) \gamma^{\lambda} \omega_{\lambda} + (g'_{00}/g) \sigma^{\lambda \nu} \stackrel{1}{=} \phi_{\lambda \nu}$$

$$+ (f/g) \gamma^{\lambda} \gamma_{5} \mathbf{\tau} \cdot \mathbf{A}_{\lambda} + (f'/g) \sigma^{\lambda \nu} \gamma_{5} \stackrel{1}{=} \mathbf{\tau} \cdot \mathbf{A}_{\lambda \nu}$$

$$+ (f_{0}/g) \gamma^{\lambda} \gamma_{5} E_{\lambda} + (f'_{00}/g) \sigma^{\lambda \nu} \gamma_{5} \stackrel{1}{=} D_{\lambda \nu} \right\} N$$
(6)

where the symbols stand for the respective vector and axial vector fields. By an argument related to the symmetry properties of the non-relativistic limit of this interaction¹¹ the ratios

$$(g'/g) = 5/3; (g'_{00}/g) = (g_{0}/g) = 1;$$

 $(f/g) = (f'/g) = (5/3\sqrt{2});$ (7)
 $(f_{0}/g) = (f'_{00}/g) = 1$

are derived.

Given these ratios, by virtue of the coupling of expression (5) the electric charge and magnetic moment of the proton and neutron can be calculated. It is found that the proton charge is +e and the neutron charge is zero. For the proton and neutron magnetic moments

$$(\mu_p/\mu_n) = -\{1 + (g/g') \ (m_g/m)\} = -1.49;$$

 $(\mu_p - \mu_n) = 1 + (g'/g) \ (2m/m_g) = 5.1$ (8)

are obtained.

The observed values are -1.46 and 4.7. The predicted and magnetic form factors will have a fall-off with momentum transfer governed by the vector meson mass. This is in qualitative agreement with experimental results.

(iii) Weak Interactions

The purely leptonic weak interactions are of the form

$$\frac{G}{\sqrt{2}} \left(\overline{6} \gamma_{\lambda} \left(1 + \gamma_{5} \right) \nu_{e} \right) \left(\overline{\mu} \gamma^{\lambda} \left(1 + \gamma_{5} \right) \nu_{\mu} \right)^{+} \tag{9}$$

with possible terms involving the electron covariant or the muon covariant quadratically. The hadrons do not couple directly to leptons or to each other. The hadron weak interactions are the consequence of the vectoraxial vector field coupling to lepton covariants. This interaction is

$$(-G/g) \cdot (m_{\varrho} \, \rho^{\lambda} + m_{A}^{2} \, A^{\lambda}) \, (\overline{\mu} \, \gamma_{\lambda} \, (1 + \gamma_{5}) \nu_{\mu} + \overline{\Theta} \, \gamma_{\lambda} \, (1 + \gamma_{5}) \nu_{e}) \quad (10)$$

By virtue of the strong interaction of expression (6), there is an effective nucleon–lepton four-fermion coupling. For small momentum transfers it can be approximated by the familiar beta decay interaction^{1,2}

$$\frac{G}{\sqrt{2}} \left(\overline{N} \gamma_{\lambda} \left(1 + g_{A} \gamma_{5} \right) \tau^{+} N \right) \left(\overline{\Theta} \gamma^{\lambda} \left(1 + \gamma_{5} \right) \nu_{e} \right) \tag{11}$$

Here the Fermi coupling constant is the same as the one occurring in the muon decay interaction in expression (9). According to expression (7) (for alternative derivation see refs. 13 and 14), the ratio of Gamow-Teller to Fermi interaction is

$$g_A = (-G_A/G_V) = (f/g) = (5/3\sqrt{2})$$
 (12)

The effective V-A four-fermion interaction is thus recovered as in the original formulation^{1,2} but with the correct ratio of the Gamow-Teller and Fermi coupling constants. When the momentum-dependent terms are considered the familiar induced pseudoscalar term¹⁵ and the weak magnetism term¹⁶ with the usual values are obtained.

Because of the electromagnetic coupling in expression (5), the fundamental principle of electric charge-current conservation demands that the neutral components of ρ and ω remain divergence-free. Thus no neutral lepton currents are expected to be present in weak interactions. None is, of course, found.

There is a degree of time reversal and CP violation in the strong interaction in expression (6) and thus in the effective nuclear beta decay interaction. This effect seems to be beyond the present experimental accuracy; in a typical beta transition the energy release is a fraction of an MeV. But even for 1 MeV energy release, the amplitude of the CP violating term is

$$(f'/f) (m_e/m_A) \simeq 10^{-3}$$
 (13)

of the normal (CP conserving) amplitude.

Using the observed value of the charged pion and muon lifetimes and by virtue of expressions (1) and (10), a relation for the absolute value of the parameter ξ and the

strong vector coupling constant g can be deduced. From expression (10), the effective pion decay interaction is

$$\frac{G\,m_A^2\,\xi}{g}\,\,\cdot\,\,\frac{1}{m_\pi}\,\,\cdot\,\,\partial^\lambda\varphi_\pi\,\,\overline{\mu}\,\,\gamma_\lambda\,(1+\gamma_5)\,\,\nu_\mu \eqno(14)$$

From the muon lifetime of 2.198×10^{-6} sec

$$G = 2.43 \times 10^{-7} \ m_{\pi}^{-2} \tag{15}$$

From the pion lifetime of 2.551×10^{-8} sec and expression (14)

$$(\xi/g) = 1.02 \times 10^{-2} \tag{16}$$

Using the divergence relation of equation (2) and the fact that the pion-nucleon coupling implied by expressions (1) and (6) is

$$\frac{1}{2}f\xi \, \overline{N} \, \gamma^{\lambda} \gamma_5 \, \partial_{\lambda} \, (\tau \cdot \varphi_{\pi}) \, N \tag{17}$$

which leads to¹⁵

$$\xi^2 = \frac{1}{2} (m_\pi/m_A)^2 = 8 \times 10^{-3} \tag{18}$$

These give

$$\xi = 0.09$$

$$g = 9.0 \tag{19}$$

The value g = 9.0 is in essential agreement with the phenomenology of strong interactions

Strange Particle Weak Interactions

For the leptonic weak decays of strange particles we extend the scheme by considering the charged strange vector and axial vector fields V_{λ} and A_{λ} on the same footing as the charged non-strange vector and axial vector fields V_{λ} and A_{λ} by the replacement

$$V_{\lambda} \to V_{\lambda} + V_{\lambda}$$

$$A_{\lambda} \to A_{\lambda} + A_{\lambda}$$
(20)

in the primary weak interaction coupling of expression (10). According to equation (1) this implies a coupling of the kaon to the charged lepton currents similar to expression (14). The ratio of kaon and pion transition rates can now be calculated to obtain

$$\frac{\Gamma\left(\mathsf{x}\to\mu\mathsf{v}\right)}{\Gamma\left(\pi\to\mu\mathsf{v}\right)} = \frac{m_\pi}{m_\mathsf{x}} \left[\frac{1-(m_\mu/m_\mathsf{x})^2}{1-(m_\mu/m_\pi)^2}\right]^2 \simeq 1.4$$

Using an experimental value of the pion lifetime and the value of the branching ratio $R=0.65\pm0.02$ for the two-body leptonic mode of the kaon, for the kaon lifetime

$$\tau(\mathbf{x}^+) \; = \; \frac{\Gamma \; (\pi \to \mu \nu)}{\Gamma \; (\mathbf{x} \to \mu \nu)} \; . \; R \; . \; \tau(\pi^+) \; = \; 1 \cdot 17 \times 10^{-8} \; \mathrm{sec}$$

is obtained which is to be compared with the experimental value⁵

$$\tau(\varkappa^+) = 1.22 \times 10^{-8} \sec$$

It is to be emphasized that this rate is predicted without making use of any new smallness parameters (contrast with ref. 18).

For the axial vector decays of hyperons it can be shown that, making use of the divergence relation of equation (2), the effective four-fermion interaction for the leptonic decays of baryons can be computed. It turns out that they are uniformly smaller than the nucleon beta decay coupling by a factor

$$\tan \theta_{\beta} = \frac{m_{\pi}}{m_{\pi}} \left(1 + \frac{M - m}{2m} \right)^{-1} \simeq 0.26$$
 (21)

where M/m is the ratio of the hyperon mass to the nucleon mass. If the requirement that there are no strange scalar particles is used it can be demanded that the strange vector fields be free of divergence

$$\partial^{\lambda} V_{\lambda} = 0$$

This implies, in turn, that (the leading terms in) the vector coupling between the baryons of different mass should vanish. Thus the vector decays of hyperons and the three-body leptonic decays of kaons both proceed by

the smaller momentum dependent couplings; it is not possible to make a simple prediction for the apparent suppression factors. Experimentally, the vector decays have an even smaller ratio to the vector beta decay coupling by a factor of 0.6 as compared with the ratio of the axial vector strengths.

Non-leptonic weak decays of baryons and mesons require a self-coupling of the vector-axial vector strange fields with the corresponding non-strange fields.

Implications for Strong Interactions

It is possible to use the present theory to compute the low energy pion-nucleon interactions (paper in preparation). The dominant contributions come from nucleon and nucleon resonance exchanges and the exchange of the vector meson. A simple calculation for the s-wave scattering lengths yields the values

$$a_1 = +0.160 \ m_{\pi}^{-1}; \ a_3 = -0.080 \ m_{\pi}^{-1}$$

in good agreement with the values obtained from experiment

$$a_1 = +0.183 \ m_{\pi}^{-1}; \ a_3 = -0.109 \ m_{\pi}^{-1}$$

Similarly, for the p-waves it can be predicted that

$$a_{11} = -0.115 \text{ m}_{\pi}^{-1}; \ a_{33} = +0.117 \ m_{\pi}^{-1}$$

 $a_{13} = a_{31} = \frac{1}{4} \ a_{11} = -0.029 \ m_{\pi}^{-1}$

These are in good agreement with the experimental values

$$\begin{array}{lll} a_{11} = -0.101 \ m_{\pi}^{-1}; \ a_{33} = +0.215 \ m_{\pi}^{-1}; \\ a_{13} = -0.029 \ m_{\pi}^{-1}; \ a_{31} = -0.038 \ m_{\pi}^{-1} \end{array}$$

For inelastic pion-nucleon resonance the present theory leads to the prediction that the I = 1/2 amplitude should be $\sqrt{10}$ times the I = 3/2 amplitude¹⁹. The experimental data have been analysed to yield20

$$(A_1/A_3) = + 3.34$$

in excellent agreement.

Mesons were suggested by Yukawa to account for nuclear forces and nuclear beta decay²¹. Within my present scheme there are many mesons, comprising the pseudoscalar, vector and pseudovector mesons. sequently, the nuclear forces which are obtained have three characteristic ranges; the largest range is the result of pion exchange, and it has been known for quite some time that the "tail" of the nuclear force is consistent with this picture. The vector and pseudovector mesons lead to shorter range potentials; but they also lead to spin-orbit forces which are essential to an understanding of the nucleon-nucleon interaction. Both in complex nuclei and for nucleon-nucleon scattering at higher energies

they were phenomenologically introduced with great

We have outlined here a theory of universal primary interactions of particles, including strong, electromagnetic and weak interactions. The most important idea is that the primary interactions of the baryons consist of the strong universal coupling to vector and axial vector fields only. Both electromagnetic and weak interactions of baryons are acquired characteristics. Thus this theory is the logical completion of the idea that the beta decay of the nucleon arose only by virtue of its coupling to the meson. Such diverse items of particle phenomenology such as nuclear magnetic moments, ratio of the Gamow Teller and Fermi coupling constants, weak magnetism, absence of neutral lepton currents, apparent suppression of strange particle leptonic decays, pion-nucleon scattering lengths and the salient features of the nuclear force are quantitatively accounted for by present theory. Such an array of satisfactory predictions leads us to study this theory seriously. A more detailed account of this theory will be published elsewhere.

I thank Professor J. Mehra for his interest and advice, Professor K. T. Mahanthappa for discussions on weak interaction physics, and Professor T. Pradham, Dr R. P. Saxena and Dr K. Raman for discussions on nucleonnucleon interaction. This work was supported by the US Atomic Energy Commission.

Role of Carotenoids in Photosynthesis of Green Plants

HENRIK LUNDEGÅRDH Research Laboratory, Penningby, Sweden

In contrast to other hypotheses, \beta-carotene is responsible for the photic reduction of triphosphopyridine nucleotide during the photosynthetic cycle of electron transfer and energy conversion in green plants.

According to current hypotheses three main systems can be distinguished in the photosynthetic cycle of electron transfer and energy conversion in green plants. illumination, pigment system III, which contains chlorophyll, carotene and possibly accessory pigments, expels electrons to the reducing system (I; pigments-ferredoxin -TPN). The oxidizing system (II; eytochromes f, b and b_3) then returns the electrons to the pigments. Photophosphorylation and oxygen production are probably largely conducted by system II. The electrons lost from cytochrome f are retrieved from the reducing system by way of a flavoprotein1. It can be shown that flavoprotein and cytochromes are operating synchronously and that the amount of reduced pyridine nucleotide (TPNH) decreases on illumination with red light which, however, primarily stimulates system II. In blue-violet light which, on the other hand, stimulates system I, the level of reduction and the amount of TPNH increase. The existence of two pathways, one which photically oxidizes cytochrome f and another which reduces the cytochromes again in the dark, was described in my first communication on the oxidation of cytochrome f by light². Recent experiments have shown that added TPNH can also be oxidized during the restoration of the reduced state of the cytochromes^{3,4} and that the reducing and oxidizing systems are conducted by two separate light reactions. This theory was earlier adopted by others also.

Many authors believe that chlorophyll is directly involved in both reactions, but this hypothesis does not explain the actual difference in their action spectra. Chlorophyll has strong bands of absorption in both the blue-violet and red regions, and experiments with added oxidants, for example, potassium ferricyanide, show a fast rate of oxygen production in both cases. Blue-violet light, however, does increase the production of TPNH more than red light. This fact proves that reactions I

and II are conducted by different pigments.

On the basis of these facts and the results of other experiments on the effect of light of chloroplast carotenoids, I have concluded that reaction I involves excitation of β -carotene and transfer of electrons to ferredoxin-TPN5.6. β -Carotene is oxidized to xanthophyll, as shown by direct determination of the ratio c (carotene)/x (xanthophyll) before and after illumination. With short exposure times of 5–10 min the total amount of carotenoids (c+x) remains fairly constant: the pigment system reduces xanthophyll through system II. This was also shown by Costes? During prolonged illumination, carotenoids may be lost, probably because the electrons coming from system I are trapped in the added oxidant during impaired reduction of the pigments.

Chloroplasts from leaves of spinach were isolated in 0.3 molar sodium chloride + 0.02 molar potassium hydrogen phosphate at pH 8.2. Photosynthetic production of oxygen was determined by means of rapid polarography ('Polarecord', Metrohm, Switzerland). The chloroplast suspension was kept in small plast tubes (about 12×20 mm) which were fitted with rubber stoppers. During illumination the tubes were placed in a cuvette with a quartz window and cooled to 1°-3° C by means of a The tubes were centrifuged before the quantity of oxygen was determined. Illumination was provided by a small 250 W projector, fitted with heat absorbing filters and Schott colour filters or interference filters. Experiments were also performed using a high intensity Bausch and Lomb monochromator and tungsten or xenon lamps.

In vitro experiments were performed using a solution of purified ferredoxin from spinach (by courtesy of Professor D. I. Arnon, Berkeley) containing 1 mg/ml. chlorophyll and a somewhat larger quantity of TPN (Sigma). β -Carotene (7 mg/ml., Sigma, type 4) was added in the form of a fine crystal powder and the mixture was exposed to a stream of bubbling nitrogen. The quartz cuvette (10×40 mm) was illuminated by the projector at room tempera-

ture.

Ferredoxin and TPN reductions were recorded spectrophotometrically. In the oxidized state, ferredoxin from spinach has a high band at about 420 nm and a lower band at about 460 nm. These bands disappear during reduction. Determinations of the band heights are hampered by the fact that the background of the whole spectrum rises from blue—green to ultraviolet. The measurements were therefore made from a straight line drawn between 400 and 500 nm. For measurement of the 340 nm band of reduced TPN, a base line was drawn between 300 and 380 nm.

Measurements of rapid reactions of systems I and II were made by an oscillographically recording scanning

spectrophotometer. Observations were made 20 msec after an electric flash^{1,8} and compared with the values just before the flash. As I have shown³, the photic response is extremely rapid (considerably below 1 msec) but the effect on the enzymes (cytochromes, ferredoxin—TPN) lasts longer because dark reactions proceed more slowly.

Action of oxidants. To interpret accurately experimental results obtained with isolated chloroplasts, it is important to realize that these chloroplasts are cut off from any co-operation with the protoplasm and cannot respire. Direct comparisons with the photosynthesis of whole leaves or whole green cells, such as by determination of the action spectrum, must therefore be made with Chloroplasts are suspended in a limited great care. quantity of medium and are provided with sufficient quantities of chlorophyll, cytochromes, ferredoxin and TPN for intense photosynthesis during 5-10 min without any visible bleaching of the chlorophyll and scarcely any loss of carotenoids. The ratio c/x is decreased but c+xremains nearly constant. For efficient oxygen production, an extraneous oxidant must be added, but, in my own experience, no extra ferredoxin is needed. Addition of ferredoxin or any other reductone of high negative potential, for example, viologen, has no special effect on unwashed chloroplasts. This means that the photolysis of water and oxygen production is coupled to the positive side of the chain, that is, the cytochromes. Hill10 showed that ferricyanide (about +0.4 V) oxidizes cytochrome fand Table 1 and Fig. 1 show that the oxidation of cytochrome f increases with rising concentration of ferricyanide, and oxygen production concomitantly is raised. Simultaneous determination of reduced ferricyanide in red light yields the theoretical value

$$\frac{\text{mole ferricyanide}}{\text{moles } O_2} = 4.$$

These experiments show that reduced ferricyanide is not re-oxidized by chlorophyll: the electrons arriving from system I (or TPNH) are thus trapped in the extraneous oxidant. This means that the chlorophyll cannot deliver new quantities of electrons for reduction of the oxidized β-carotene; a fact that during prolonged illumination (more than 10 min) leads to retarded photosynthesis and probably contributes to the loss of carotenoids by oxidation.

It follows from these observations that the transition,

cytochrome $f^{\underline{e}}$ chlorophyll, is one of the most sensitive points in the cycle. An illustration of this sensitivity is the earlier observed fact that, during increased mechanical or sonic disintegration of the chloroplasts, linkage of the cytochromes with the other components of the stroma is the first to be broken. That electrons nevertheless may pass over from cytochrome f to chlorophyll is shown during very strong illumination, for example, by an electric flash. The experiments also show that, at an extra excitation of system I, for example, by blue light, the ratio ferricyanide/oxygen decreases to less than 4, obviously because some electrons are now bypassing the

extraneous oxidant. Weak oxygen production may occasionally also occur without addition of ferricyanide.

According to the circumstances mentioned, photosynthetic production of oxygen by isolated chloroplasts depends not only on the oxidant but also on the ability of system I to deliver electrons. This means that the stream of electrons to system II will be more rapidly exhausted in red than in blue light. A comparison between oxygen production during the first 10 min and during 30 min shows a much more pronounced decline under red light (Table 2). Green light, which is relatively less absorbed by chlorophyll than by β-carotene, supports photosynthesis for nearly as long as blue light.

A suspension of unwashed chloroplasts kept in the dark contains a certain quantity of TPNH which, because of its solubility in water, leaks out into the medium, even if some of it is presumably bound to the structure (or structurally linked enzymes). Table 3 shows that during illumination by red light the quantity decreases, whereas Table 2. it increases in blue light. This is a good illustration of the existence of two separate light reactions; blue light conducting system I and red light conducting the oxidation of TPNH through system II.

Time course of the excitations. An electric flash lasts for only about 0.1 msec, but, for quantitative oscillographic measurements, at least a few msec are needed (the disturbing higher frequencies must be cut off by damping). Continuous recording of the immediate effect and the after effect of a flash shows that the instantaneous oxidation of cytochrome f (at 554 nm) and reduction of TPN (at 340 nm) is followed by an after effect lasting a maximum of up to 100-150 msec before the original 75 per cent reduction of cytochrome f is restored (see Figs. 1A and 2). The time course of the after effect of a flash varies with the conditions of the sample, its age, degree of washing, etc. Figs. 1 and 2 show examples of a rapid and a slower wave of the process. That not only oxidation but also reduction of cytochrome f by one flash can be measured depends on the fact that the cytochromes in the dark are usually only reduced to about 60-70 per cent, not to 100 per cent as erroneously claimed by some authors. As shown in Fig. 2, the time course of cytochrome f oxidation is dependent on the colour of the flash. The optimal effect of red light—that is, exidation of cytochrome f—is attained at about 140 msec, whereas the effect of blue light, namely, reduction of cytochrome f. is maximal at about 200 msec.

The comparatively slow development of the after effect of a flash illustrates the large difference in time course between the photic excitation and the enzyme reactions (compare ref. 9). This gives the impression that the initial photic excitation is temporarily stored by some intermediate factor. The different effects of blue and rod light point either to a slower transference between β-carotene and ferredoxin in system I or to a damping influence of the chain of enzymes which transfers electrons from system I to system II. The chain of oxidation reduction enzymes acts in all circumstances as a pacemaker of the photosynthesis. This, of course, has nothing to do with the fact that, at moderate light intensity, there is a linear relation between light and photosynthesis, because the transference of the initial excitation to the chain of enzymes and the activity of these now run at the same speed.

In vitro Reduction of Ferredoxin-TPN by \$\beta\$-Carotene

As shown before, β -carotene in the form of insoluble crystals or dissolved in chloroform acts as a photoreductone for ferredoxin even if the latter is in aqueous solution. Transfer of electrons occurs at the contact surface. The first experiments were carried out during illumination in blue light (BG 12 or 25) and the mixture was exposed to a stream of vigorously bubbling nitrogen^{5,6}. The reduced ferredoxin reduces TPN. This model experiment strongly supports the hypothesis that β -carotene is the photoactive factor of system I. To elucidate the action spectrum of the process different model experiments were carried out in green and red light. The results are shown in Fig. 3.

The new observations corroborate the previous results, namely, strong reduction of ferredoxin and a clear formation of TPNH in blue light. They also show a significant positive effect of green light and an effect of red light (>625 nm) which amounts to about 30-50 per cent of that in blue light. Even in the dark some reduction can be observed, but these results are not yet significant.

Careful examination of the absorption spectrum of β-carotene shows no absorption band in red but a 10–15 per cent absorption was observed in infrared and chloroplasts show a measurable scattering of the light which can also be developed in a suspension of very small crystals. On these grounds, there is no reason for denying the possibility of a limited photic excitation also in the red region. Previous investigations (see Fig. 3) also showed that red light has significant effects on β-carotene in solution, notably a characteristic negative peak at about 510 nm. This peak is considerably more pronounced after illumination with blue light.

Influence of pre-illumination on oxygen production. Direct polarographic measurements of oxygen were made in the cooled chloroplast suspension. As shown in Table 4, blue light (450 nm) with a photosynthetic effect of 21–26 (measured as the deflexion of the polarographic response to oxygen) stimulates the effect of the subsequent exposure to 680 nm (the top of the red absorption band) from 17–26 to 34, whereas the effect of 450 nm following 680 nm is a strong inhibition, from 21–26 to only 7. The effect of pre-illumination with 550 nm (56–57) on 680 nm is less significant (from 17–26 to 17), whereas the effect of 680 nm on 550 nm is a retardation from 56–57 to 41. Still stronger is the retarding effect of 450 nm on 550 nm (decreasing from 56–57 to 23) whereas 550 nm seemed to have no effect on 450 nm.

The flash experiments showed that red light stimulates system Π but retards system I, resulting in an increase of the level of oxidation in the whole cycle and a shortage of TPNH produced. Blue light (450 nm) has the reverse effect, that is, it increases the level of reduction in the cycle and concomitantly facilitates a following activity of system II. Green light is characterized by a high quantum efficiency¹ and stimulates both systems I and II. System I is probably stimulated as a result of absorption by β-carotene in green light and system II is possibly stimulated by means of the cytochromes. The influence of a pre-illumination with green light on the effects of 450 and 680 nm is less significant.

The role of carotenoids in photosynthesis is illustrated by the direct observation of reduction of ferredoxin-TPN

in vitro, by the appearance of a negative band at 500–520 nm in chloroplasts and in illuminated β -carotene by the synchronous decrease of the ratio c/x with the rate of photosynthesis, and by the fact that all these reactions are primarily sensitive to blue light. These results support more strongly my hypothesis that, in system I, β -carotene is responsible for the photic reduction of TPN, than the hypothesis that chlorophyll is directly responsible, not only for system II but also for system I. That chlorophyll is reduced by system II is shown by other experimental results and it is likely that reduced chlorophyll when illuminated reduces xanthophyll to β -carotene and thus completes the cycle. Our experiments on changes in the state of oxidation-reduction of the cycle caused by illumination with different colours illustrate the separate activities of systems I and II.

The extreme reactivity of β-carotene^{7,12}, and the fact that isolated chloroplasts are exposed to external influences much more than are those in the intact cell, could cause reactions which lie outside the photosynthetic cycle, for example, oxidative loss of carotene during oxygenation or prolonged illumination⁸.

Loss of total carotenoids during illumination of isolated chloroplasts starts with exposures lasting longer than 10 min in strong light but is observed chiefly in white or red light. Blue light, however, counteracts the losses (Table 3). In addition to this photic consumption of carotene there may be an irreversible oxidation in the dark during oxygenation. It could be experimentally shown that the decrease in the ratio c/x is observed independently of photophosphorylation and photic oxygen production—more facts which support the concept of separate activity of the systems I and II.

This detailed experimental analysis of the conditions and activities in isolated chloroplasts clearly shows the irrelevance of certain objections against the thesis of β -carotene as an active promoter of system I. The fact that during shorter periods strong photosynthetic oxygen production proceeds in red light is satisfactorily explained by an independent activity of system II at the expense of stored TPNH, and a moderate activity of system I also in red light. The rash conclusion that red light does not affect β -carotene is at variance with our direct observations in connexion with the model experiments. Oxygen production of illuminated chloroplasts is furthermore chiefly a property of system II and its supply of electrons from TPNH—a certain quantity of which is present in

the chloroplasts from the start. Its consumption during prolonged illumination with red light is shown both directly and indirectly (Tables 1 and 3).

Triads in Foetal Skeletal Muscle

SHEPPARD M. WALKER G. RANDOLPH SCHRODT

Departments of Physiology and Pathology, University of Louisville School of Medicine In the gastrocnemius muscle of the rat foetus longitudinally oriented triads were often seen near A-I junctions. This suggests that there is a change from longitudinal to transverse orientation during the development of skeletal muscle.

In vertebrate skeletal muscle a triad contains a central element formed from the T system (T) and two lateral elements formed from the terminal segments of the sarcoplasmic reticulum (SR). The T system is continuous with the sarcolemma at the Z level of the line in certain fish1 and frog 2 muscle and at the level of the A-I junction in rat^3 muscle. The triads are located at the Z level of the line in fish and frog muscle and near the A-I junction in rat muscle. Virtually all the triads in vertebrate skeletal muscle of adult animals are oriented transversely, with a few sparsely distributed longitudinal connexions between the transversely oriented \check{T} system⁴. A notable exception is the observation⁵ that triads are frequently oriented longitudinally at the level of the Z line in slow fibres of frog muscle. The space between apposed mem-branes of T and SR in transverse and in longitudinal triads is remarkably constant and is about 100 Å. Revel⁴ described rather regular periodicity of dense bridges traversing this space in bat muscle fibres. Similar dense bridges were reported3 for rat muscle fibres and evidence that these bridges are connexions between T and SR has been presented^{6,7}. The terminal segments of the sarcoplasmic reticulum are frequently called cisternae, but several investigations^{2,4,8-10} have noted electron-opaque material in SR. Structures resembling a membrane within SR have been reported11 for rat muscle. In this article the abbreviation SR applies specifically to the lateral elements of the triad.

In a recent electron microscope study of the morphogenesis of rat skeletal muscle, sarcoplasmic reticulum between the developing fibrils was observed in 16.5-20 day rat foetuses, but no triads were reported12. In lightmicroscope investigations on newborn mice and foetal guinea-pigs, Verattii13 found that the mesh of reticulum is oriented predominantly in the direction of the longitudinal axis of the fibre and rarely in the transverse direction. He observed a regular reticulum, transversely oriented, in fibres from adult mice13. The contrast between the appearance under the light microscope of muscle fibre reticulum of newborn mice and of adult mice suggested that transversely oriented triads typical of adult muscle are rare in foetal muscle. microscopy of skeletal muscle fibres from foetal rats has shown that triads are relatively scarce, with more triads oriented longitudinally than transversely.

The age of rat foetuses was determined by the detection of sperm in the vaginal smear of the mother. The observa-

tions were made on eight 19 day foetuses. Results were compared with those of many previous electron microscope examinations of adult rat muscle fibres. In the case of rat foetuses the entire gastroenemius muscle was fixed, but with adult animals small bundles of fibres were removed from the gastrocnemius muscle of animals anaesthetized with 'Nembutal'. The bundles of fibres were tied to 'Plexiglas' stays and fixed in glutaraldehyde by a slightly modified version of the method of Sabatini et al.14. The tissues were post-fixed in osmium tetroxide by the Palade method, as modified by Caulfield 15. fibres were stained with uranyl acetate during dehydration with alcohol, embedded in 'Maraglas' and sectioned with an LKB microtome. The sections were triple stained with lead, uranyl acetate and lead. A modification of the Reynolds method 16 was used for lead staining. Sections exhibiting grey interference colours were examined with a Siemens 'Elmiskop IA' electron microscope.

Triads are quite easily identified in adult rat muscle fibres because they are almost invariably found transversely oriented between the fibrils near the junctions of the A and I bands. In longitudinal sections, through the centres of two neighbouring fibrils, a cross-section of a triad can be seen. In a longitudinal section of a fibre, with the plane of section passing along the face of a fibril, a longitudinal section of a triad can be seen (Fig. 1). Location and identification of triads in foetal muscle are difficult for several reasons. First, the fibres are small and fragile. Second, the interfibrillar spaces are relatively large and they contain a thick distribution of electronopaque granules. Third, the triads are usually oriented longitudinally. When they are thus oriented they apparently do not encircle the fibrils. Fourth, transverse triads are rare and longitudinal triads are sparsely distributed. There are three structural characteristics of triads in rat muscle fibres that can be seen equally well in transversely and longitudinally oriented triads. These characteristics are: (a) the approximate 100 Å between apposed membranes of T and SR; (b) dense bridges across this space; and (c) electron-opaque material within SR which contrasts rather sharply with the less opaque appearance of material within T. In Fig. 2 are shown the most unusual findings in foetal muscle fibres, that is, a transversely oriented triad. The triad in the upper right side (star) is shown in cross-section. The extent of the transverse orientation around the circumference of the fibril is in doubt because a section of a triad on the other side of the

fibril is not seen. In the lower left side of Fig. 2 an approximate longitudinal section of a transversely oriented triad (asterisk) is seen, and a segment of considerable length is shown in transverse orientation. It is interesting that the transversely oriented triads are always found near the level of the A-I junctions. What is more striking, however, is the observation that the longitudinally oriented triads are also near the A-I junctions (Fig. 3). Triads thus oriented might be expected to be distributed randomly along the interfibrillar space with no specific location in the sarcomere. It is true that the location of a triad in relation to the neighbouring fibril cannot always be definitely established. Spurious appearances may be created by distortion of alignment of fibrils in juxtaposition, and an example of such distortion is shown in Fig. 4. If the position of the triad (star) is judged in relation to the fibril in the left side of the figure, it seems to be near the M line. On the other hand, the triad considered in relation to the fibril near it in the right side of the figure is near the A-I junction. The inset in the upper right side of Fig. 4 shows a high magnification of the triad that reveals three characteristics of triads used for identification. The approximate 100 Å spaces (vertical arrows) between T and SR are visible on both sides of T. Dense bridges across the space on the left side of T can be seen by close inspection. The difficulties encountered in attempting to find several triads in a single section are illustrated in Fig. 5. There are two structures which seem certain to be triads (stars). The structures designated by asterisks are judged to be triads. This judgment is supported by the locations of the questionable structures

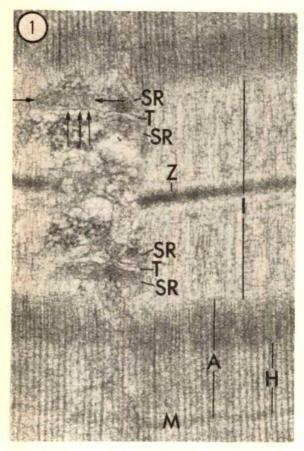

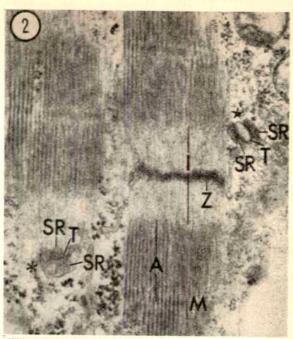

Fig. 1. Electron micrograph of adult rat gastrocnemius muscle fibre showing two transversely oriented triads in a longitudinal section of the fibre. The vertical arrows are directed toward dense bridges across the space between a terminal segment of the sarcoplasmic reticulum (SR) and the T system (T). The horizontal arrows are directed toward membrane-like structures within SR. Z represents the Z line, M the M line, M line, M line, M line, M line, M line M line

Fig. 3. Longitudinal section of a foetal muscle fibre showing a triad that appears to be longitudinally oriented. Note the intense staining of SR. (\times c. 32,000.)

near the $A{-}I$ junctions. Fig. 5 also illustrates the complex system of sarcotubules (ST) found in the interfibrillar spaces of rat foetal muscle. In spite of the thick distribution of dense granules the interlaced tubules can be seen in some places. It is clear that the two membranous systems (T system and sarcoplasmic reticulum) cannot be distinguished in the maze of tubules labelled as sarcotubules. In fibres from adult rats (Fig. 1) the T system is confined almost entirely to its transverse orientation in the triads near the $A{-}I$ junctions. It is obvious from examination of extensions of the T system beyond longitudinal triads (arrow in Fig. 5) that such confinement does not exist in rat foetal muscle fibres.

The use of location near the A–I junctions to aid interpretation of electron-opaque structures as triads is illustrated in Fig. 6. All the structures indicated by stars occupy similar positions relative to the A–I junctions of the fibril in the left side of Fig. 6. The second structure from the top shows the central element (T) and one lateral element (SR) as they might be seen in an unlateral element (SR) as they might be seen in an uncated by stars show electron-opaque material comparable with that seen in lateral elements of triads. Whether the absence of one or more components of the triad is peculiar to this unfavourable section or is a result of incomplete development is not known. In Figs. 5 and 6 the findings that longitudinally oriented triads are not

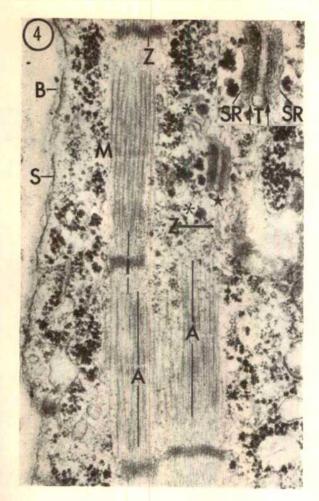

Fig. 4. Longitudinal section of a foetal fibre showing a triad (star) oriented longitudinally. The heavy horizontal line indicates the position of the Z line for the fibril near the triad. Arrows are directed toward spaces between T and SR in the inset of the triad in the upper right side of the figure. Asterisks are placed on the left side of latex spheres about 880 Å in diameter. B. Basement membrane; S, sarcolemma. (\times e, 32,000; inset, \times e, 51,000.)

located at the level of the Z line of the sarcomere are shown. Characteristics of typical fibrils in the 19 day foetal muscle fibre are illustrated in Fig. 6. The average diameter of the largest fibrils in foetal fibres is about equal to the average diameter of fibrils in adult rat muscle fibres. It is interesting that fibrils may attain full size in the 19 day foetus, while the diameter of the fibre is only a fraction of that in the adult. The average fibre diameter is about 10μ in the 19 day foetus, and $40-50\mu$ in the adult. The length of the A band in foetal muscle is equal to that in the adult, even in the thinnest fibrils observed. The M lines are sharply defined and well developed.

We tried to find continuity of the T system with the sarcolemma and extracellular fluid in foetal fibres. Invaginations of the sarcolemma near the level of the A-I junction were found at a few points, but we saw no connexions of these invaginated membranes with lateral elements of triads. In one case, a continuity of the sarcolemma with the membranes of a T system tubule was observed (Fig. 7). Although no opening from T to the extracellular fluid is shown, it seems probable that a more favourable section would have revealed one. Investigations^{3,6,17} of adult rat muscle fibres employing methods of preparation similar to those described here have shown narrow openings through the sarcolemma into enlarged tubules of the T system near the level of the A-I junction. In the adult the subsarcolemmal triads are transversely

oriented. It can be seen in Fig. 7 that the plane of apposition between T and SR is oriented longitudinally Opacity at the site of apposition is very intense and might account for failure to see the characteristic space between apposed membranes of T and SR. On the other hand, an unfavourable plane of section might explain the failure. Nevertheless, the electron-opaque material in the lateral element (SR) and its virtual absence in the central element (T) seem to warrant the conclusion that two of the components of a triad are shown in Fig. 7. It is difficult to make good preparations of membrane-like structures in lateral elements of triads in foetal muscle fibres. The membrane-like structures as shown within SR of adult rat fibres (Fig. 1) have not been clearly demonstrated for foetal rats. The electron-opaque material within SR of fibres from foetal rats, however, might be homologous with the membrane-like structures observed in adult rats11.

These observations pose two questions of particular interest. The first concerns development of the triad; the second excitation–contraction coupling. The prevalence of longitudinally oriented triads and their frequent location near the A–I junctions in skeletal muscle fibres of foetal rats are striking and unexpected findings. So far, observations can only suggest that there is a transition of triad orientation from the longitudinal to the transverse direction during development of rat muscle. This idea is supported by the similarity of sarcolemmal and T system connexions in adult and foetal rats. It is obvious that triad development should be studied in the muscle fibres of newborn and young

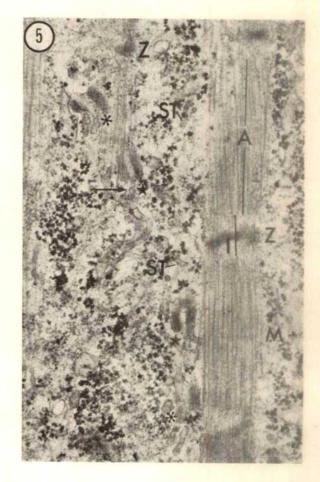

Fig. 5. Longitudinal section of foetal fibre showing triads (stars) and apparent triads (asterisks) oriented longitudinally and located near A-I junctions. The arrow is directed toward an extension of T. ST, Sarcotubules. (x c, 32,000.)

growing rats, and more information about the distribution of the T system would be useful in connexion with these studies. The T system might be traced with ferritin particles2,5, "calcium staining"4 or with potassium pyroantimonate used for localization of sodium18.

The suggestion that the triads are related to inward conduction of excitation from the fibre surface has been made¹⁹ and substantially supported^{20,21}. The T system has been specifically implicated in inward conduction of excitation by virtue of its observed connexions with the sarcolemma¹⁻³. On the other hand, lateral elements of the triads have been suggested to take part in the excitation-contraction coupling aspect of muscle function. Small quantities of calcium ions placed on exposed fibrils are known to induce contraction²². Observations^{23,24} that frog skeletal muscle fibres treated with oxalate show precipitation of calcium ions chiefly in the lateral elements of triads support the idea that these ions are accumulated in these elements. It has been suggested that accumulated calcium ions are released from the lateral elements by inward conduction of excitation along the central element (T system). In the light of various findings and suggestions it seems reasonable to suppose that changes in the structure of triads during the development of muscle fibres might be associated with changes in latent period,

speed of contraction and duration of contraction in response to a single stimulus. Buller, Eccles and Eccles²⁵ have shown that fast muscles, like the flexor digitorum longus of the kitten, show an increase in speed of contraction and a decrease in contraction time of the twitch response during the first 4 weeks after birth. It would be interesting to find out whether growing kittens show changes in triad development which might be correlated with changes in the twitch response.

LETTERS TO THE EDITOR

PLANETARY SCIENCE

Intensity of the Earth's Magnetic Field in the Geological Past

RECENTLY, Krs1,2 has obtained two estimates of the Permo-Carboniferous geomagnetic field intensity from cassiterite, and one estimate of the Permian field intensity from ignimbrite, in central Europe, using the method developed by Thellier and Thellier³. Both the Permo-Carboniferous values (0.50 oersteds and 0.60 oersteds at lat. $50\cdot12^{\circ}$ N., long. $12\cdot80^{\circ}$ E.; maximum error ± 10 per cent) and the Permian value (0.50 ± 0.03) oersteds at lat. 50.63° N., long. 16.30° E.) were similar to the present field intensity in the same region (0.482 oersteds), the implication being that the Earth's field intensity has not changed appreciably since the Permo-Carboniferous. Furthermore, because the cassiterite was obtained from a greisen body, Krs considered that its thermoremanent magnetization was acquired over a period long enough to average out secular variations in intensity. The quoted Permo-Carboniferous field intensity estimates were thus thought to represent the mean geomagnetic field rather than the instantaneous field corresponding to a certain point on the secular variation curve.

Although the Permo-Carboniferous, Permian and present field intensities in central Europe may be similar, this does not indicate that the geomagnetic dipole moment has remained approximately constant over the past 270×10^{6} yr or so, because no account has been taken of the site latitude change during this period. The palaeomagnetic directions for the cassiterites4 (declination 207°, inclination +11°) and for the ignimbrite² (declination 192°, inclination -3°) indicate more southerly site latitudes at the time of acquisition of the respective thermoremanent magnetizations. Because the field intensity produced at the Earth's surface by the geomagnetic dipole varies with geomagnetic latitude, the field intensity values obtained by Krs indicate ancient dipole moments higher than the present $(8.0 \times 10^{25} \text{ gauss cm}^3)$. Virtual dipole moments⁵ calculated using these ancient field intensities and palaeomagnetic inclinations are 12.2×10^{25} gauss cm³ and 14·6×10²⁵ gauss cm³ for the Permo-Carboniferous and 12.8×10^{25} gauss cm² for the Permian, all of which are over 50 per cent higher than the present dipole moment.

A second point arises in comparing the new virtual dipole moments from cassiterite and ignimbrite with those previously published. Fig. 1a shows all virtual dipole moments covering the geological time scale (defined here as greater than 10^4 yr) available up to June 1967 (ref. 6). The new virtual dipole moments from cassiterite (open circles) and ignimbrite (cross) are differentiated symbolically from the rest of the data. Fig. 1b shows the trend curves based on data in Fig. 1a. Curve (1) is the previously published curve⁵ based on the mean virtual dipole moments from sets of rocks containing ten or more separate rock units; curve (2) is the mean curve for all data, obtained by averaging virtual dipole moments and ages in 100×10^6 yr intervals; curve (3) is the least squares regression curve for all data assuming a second order variation.

The equation determined for curve (3) is

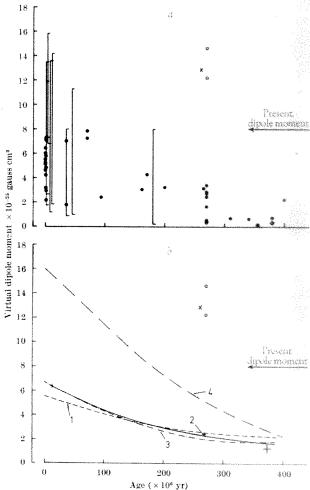

$$P(10^{-25}) = 6.76 - 2.86 (10^{-2}) t + 4.05 (10^{-5}) t^{2}$$

where P is the virtual dipole moment (gauss cm³) at time t (million years) from the present. Curve (4) is the

upper boundary of data in Fig. 1a excluding the virtual dipole moments from cassiterite and ignimbrite.

Curves (2) and (3) agree closely. Curve (1) agrees less well with these, but is not based on all the data. All three curves indicate a gradual increase of mean geomagnetic dipole moment with time by at least a factor of two over the last 400×10^6 yr. The upper boundary, curve (4), suggests further that the spread of virtual dipole moments decreases with age. Back to at least 300×10^6 yr, curve (4) lies $(150\pm20$ per cent) higher than the mean curves (2) and (3). If the spread of virtual dipole moments is chiefly caused by fluctuation of the main dipole the results suggest that the maximum amplitude of this fluctuation is approximately proportional to the mean dipole moment.

The new virtual dipole moments from cassiterite and ignimbrite seem, however, to be inconsistent with previously published data. They are considerably higher than the present dipole moment, whereas the mean curves over the whole range, and all other individual virtual dipole moments obtained so far from rocks older than 80×10^6 yr, lie below the present moment. Accepting curve (4) as a rough guide to the maximum dipole fluctua-

Age (× 10^4 yr) Fig. 1. a. Virtual dipole moments for geological time (greater than 10^4 yr) from the literature. Solid circles represent virtual dipole moments from separate rock units in cases where less than ten such units have been measured; vertical lines represent the range of virtual dipole moments in cases where ten or more units have been measured. Open circles represent virtual dipole moments from cassiterites'; the cross represents virtual dipole moments from ignimbrite'. Ages according to Holmes' revised time scale', except in a few cases where radioactive ages are available. b. Trend curves based on data in a. (1) Previously published curve' based only on virtual dipole moments from sets of ten or more rock units; (2) mean curve for all data (except cassiferite and ignimbrite) obtained by averaging virtual dipole moments and ages in 100×10^4 yr intervals and constructed by eye (error bars represent standard errors); (3) regression curve for all data used for curve (2) assuming second order variation; (4) upper boundary of all data except cassiterite and ignimbrite.

tion amplitude would mean that ultimately all virtual dipole moments obtained from rocks older than about 200 × 10° yr should be smaller than the present dipole moment. If the virtual dipole moments from cassiterite represent mean values2, the discrepancy between them and curves (2) and (3) amounts to a factor of about 7. Krs's suggestion, however, that secular variation had been averaged out in the cassiterite thermoremanent magnetization presumably referred to secular variation of the nondipole field rather than of the dipole field, in which case the virtual dipole moments from cassiterite are not mean values in the same sense that curves (2) and (3) represent the variation of mean virtual dipole moments. But, even if the eassiterite virtual dipole moments are "instantaneous" values with respect to dipole fluctuations, they still seem to be inconsistent with the pattern of such fluctuation as defined by the boundary curve (4).

In view of the general paucity of data from rocks older than 50×10^6 yr, it is perhaps too soon to say that this inconsistency necessarily implies validity of all virtual dipole moments except those from cassiterite and ignimbrite. Krs^{1,2} has shown that both the cassiterite and ignimbrite used by him possessed exceptionally high palaeomagnetic stability. Furthermore, there is still some doubt about whether the apparent increase of mean geomagnetic dipole moment with time represents a real increase or whether it arises merely through gradual decay of rock magnetization over geological time. It is also possible that the natural magnetization in some of the older rocks analysed may have been chemical rather than thermal, in which case the experimental method is not valid7.

The tentative conclusions that the mean geomagnetic dipole moment has been increasing gradually over the past 400×10^6 yr and that the amplitude of dipole fluctuations has also been increasing are based on the bulk of data currently available. When more data have been obtained these conclusions may have to be revised.

I wish to thank NATO for a fellowship during the tenure of which this contribution was prepared.

Effect of the Tunguska Meteor and Sunspots on Radiocarbon in Tree Rings

SEVERAL hypotheses have been advanced to explain the peculiar circumstances associated with the fall of the Tunguska Meteor on June 30, 1908, in Siberia (lat. 60° 55′ N., long. 101° 57′ E.). An exhaustive description of the phenomena is given by Krinov¹. Especially puzzling is the apparent absence of a meteoric crater, but Krinov² does report some recent analyses of soil in the region which show nickeliferous iron and silicate globules.

Cowan et al.3 have discussed the possibility of the phenomena being produced by the annihilation of antimatter in the atmosphere. They have tried to measure the increase in atmospheric carbon-14 which should have been produced by the neutrons generated in the process and consequently recorded in tree rings. Venkatavaradan4 has discussed the measurements and has suggested that they correlated with the solar activity cycle.

^{*} Relative deviation in the carbon-13/earbon-12 ratio from the PDB standard sample

This communication describes new measurements of radiocarbon in tree rings, with higher accuracy. results show no significant deviations which could be correlated either with the Tunguska meteor or with the sunspot cycle.

Eleven samples have been analysed. Nine were individual tree rings, and the other two contained two and three rings, respectively. All of them were taken from a section of the same tree, a poplar, Populus balsamifera (supplied by S. Westin, of the Norges Tekniske Høgskole, Trondheim, Norway). The tree grew in a windy place outside Trondheim (lat. 63° 25′ N., long. 10° 26′ E.). It was felled during the spring of 1957. For each analysis 30 g of wood was treated successively with diluted acid, alkali and acid. It was then burned to form carbon dioxide, which was purified and used as the counting gas in a proportional counter with a volume of about The carbon-13/carbon-12 ratio of the gas was measured and used to correct for variations in isotopic fractionation5.

The reference activity used was 0.95 of the National Bureau of Standards oxalic acid standard, which was known for the counter with a σ (standard error) of $\pm\,2\cdot2$ per mil. The activity of each sample was corrected for age to 1950 using a radiocarbon half life of 5,730 yr. The results are given in the last column of Table 1 and plotted in Fig. 1.

The sloping line in Fig. 1 is the least squares fit to the individual measurements. It shows a decrease in the carbon-14 activity of 0.35 per mil/year, during the time_{\odot} span covered. This is about twice as large as Fergusson's value⁶. The difference may be caused by a local effect which is at present being investigated.

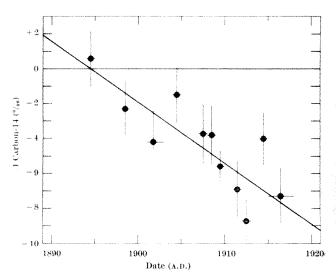

Fig. 1. Deviation of the carbon-14 activity in tree rings. The sloping line is the least squares fit to the points, the slope being caused by industrial dilution and secular variation effects.

[†] Deviation of carbon-14 activity corrected for isotopic fractionation: $^{13}\text{C} = \delta^{14}\text{C} - 2(\delta^{13}\text{C} + 25)(1 + \delta^{13}\text{C} \times 10^{-3})$ where $\delta^{14}\text{C}$ is the deviation of the age corrected activity of the sample.

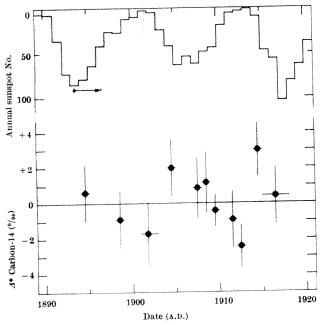

Fig. 2. Deviation of the carbon-14 activity of the tree ring samples relative to the sloping line in Fig. 1; and the annual sunspot number (solar activity). The atmospheric radiocarbon concentration should be proportional to the upper curve, with a maximum allowable phase shift as indicated by the arrow.

In Fig. 2, the same measurements are plotted with reference to the sloping line. Thus the points represent the carbon-14 deviations referred to the average activity of the atmosphere. In the same figure the annual sunspot number' is plotted with an inverted ordinate axis, to allow a direct comparison of the carbon-14 deviations with the fluctuations in the production rate of the isotope⁸.

From theoretical considerations Cowan et al.3 estimate an increase of 7 per cent for the global atmospheric content of carbon-14 as a consequence of the interaction of a mass of anti-matter large enough to produce the energy release of the Tunguska meteor. Marshall⁹ agrees with them, but Gentry¹⁰ calculates only a 2.4 per mil increase. Cowan et al. report having measured an increase of about 1 per cent for the carbon-14 concentration in the atmosphere for 1909*, the accuracy of each measurement being ±5 per mil. We do not understand their corrections for isotopic fractionation so it is impossible to give the exact magnitude of the deviation measured by them. According to Gentry, their result does not contradict his estimation, and consequently his hypothesis that the Tunguska meteor consisted of anti-matter.

From our results shown in Figs. 1 and 2, it is concluded that no deviations larger than 3 per mil have been measured, and that any possible deviation around 1909 must be smaller than about 3 per mil (for a degree of certainty of 30). Thus if the explosion was caused by annihilation of anti-matter, the first mentioned calculation has not been experimentally verified.

Lingenfelter⁸ has calculated the amplitude of the variations in the rate of production of carbon-14 by cosmic ray neutrons, assuming that the galactic component of the cosmic radiation is modulated by the solar activity. The amplitude of the atmospheric carbon-14 variations can be obtained by dividing that amplitude with the attenuation coefficient deduced from Houtermans¹¹. A maximum value of about 2 per mil results for the cycles represented in Fig. 2. The maximum phase shift which is permissible is one-quarter of a period, that is, about 3 yr. This shift

is indicated by an arrow in Fig. 2. Although there is some suggestion of periodicity in the results, the small amplitude of about 4 per mil does not allow any definite conclusion to be drawn except that the effect must be smaller than this. A much higher accuracy would be needed to detect the expected variations within an individual sunspot cycle with any certainty.

Topography and Heat Flow of the Fiii Plateau

THE Fiji Plateau is an extensive region at a depth intermediate between continent and ocean basins. Above it rise the islands of Fiji where acidic plutonic rocks occur within an ocean basin in a tectonic setting which can only be compared with the granitic Seychelles Islands in the deep western Indian Ocean. The results of the few seismic refraction lines run on the plateau indicate a variable crust of intermediate thickness¹. Thus the Fiji Plateau is an unusually interesting and promising region for tectonic studies. In the spring and summer of 1967, the Scripps Institution of Oceanography expedition Nova studied this region. In this preliminary communication we discuss results in topography and heat flow and suggest a relationship between them.

Twenty-five measurements of heat flow were made from R.V. Horizon and three from R.V. Argo during July Nineteen previous measurements taken and August. during the Scripps Institution of Oceanography expeditions Capricorn and Proa are also considereds, present measurements were all taken with a long, thin, Bullard-type probe, 2.0 cm in diameter and 2.3 m long, which penetrates the top few metres of the sediment. Three elements, which were sensitive to temperature, spaced I m apart enabled us to measure two different temperature gradients in the sediment. A fourth thermistor above the instrument package measured the absolute temperature of the superjacent sea water. Conductivities of the sediment penetrated were determined by the transient needle probe method4 on cores taken nearby. When such a core was not available, the weighted mean of nearby conductivity values was used. measured conductivities for the plateau differ very little, so it is unlikely that the assumed values introduce a significant error.

The Fiji Plateau ranges in platform depth from about 1,000 to 1,700 fathoms and west of Fiji the general trend of contours is north to south. The surface is quite irregular

^{*} Suess measured 0 ± 6 per mil for a tree ring dated 1908 (ref. 12). We think that the peak of the carbon-14 increase should be sought in the tree ring of 1909. Although the Tunguska event happened in 1908, it was already late in the season 19 and it is necessary to add some months delay for atmospheric transport 14.

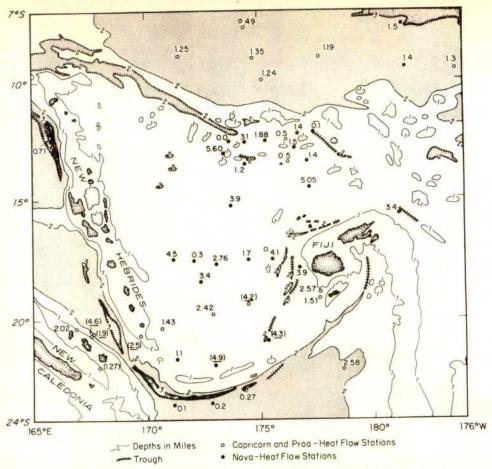

Fig. 1. Heat flow and bathymetry of the Fiji Plateau. Stations with a measured conductivity have two figures after the decimal point while those with an estimated conductivity have only one. Stations showing a partial penetration are underlined and those showing a tilt of greater than 30° are in parentheses.

on a small scale, and sub-bottom profile records show a thin but apparently uniform blanket of sediment. A few volcanic seamounts rise above the central region of the plateau and a few fault troughs cut into it. In general, it is rather subdued in aspect, seems old and is only slightly active seismically. A zone of en echelon troughs and ridges, resembling the crest of the Mid-Atlantic or Gorda Ridges lies just west and north of Viti Levu Island. This zone is seismically active and the north-south section seems to be the result of active rifting of the sea floor. Although of intense topographic relief, the zone lacks corresponding magnetic anomalies while the subdued plateau elsewhere has anomalies of several hundred gammas and an apparent

wavelength of tens of miles. It is not yet known whether the anomalies on the plateau are linear like those associated with the mid-ocean ridge system.

The great relief of the margins of the plateau contrasts markedly with the subdued centre. To the west and east are the active island arcs of the New Hebrides and Tonga. To the north is a zone of north-westerly fault troughs and large volcanoes, many of which are drowned atolls6 of Tertiary age, and the island of Rotuma which has youthful ash cones and virtually uncroded lava flows. To the south is the Hunter Fracture Zone identified by Hess and Maxwell7 and first surveyed by Horizon during the Nova Expedition. The western part of the fracture zone curves in a smooth are into the southern section of the New Hebrides Trench. Farther east, a regional difference in depth of more than a mile is marked by en echelon troughs as much as 3,800 fathoms deep. The fracture zone continues east to Vanua Levu Island and includes Tertiary volcanoes as well as the active volcanoes of Matthew and Hunter Islands. Despite the great relief, neither the northern nor the southern zones of boundary faulting is seismically active.

The heat flow measurements range from 0.0 to 5.60 µcal/cm²/sec (Fig. 1). The central subdued topographic region of the Fiji Plateau has a uniformly high heat flow; discounting partial penetrations, it has a mean value of 2.43 with a standard deviation of 1.56 µcal/cm²/sec. In contrast, the mountainous northern and southern bound-

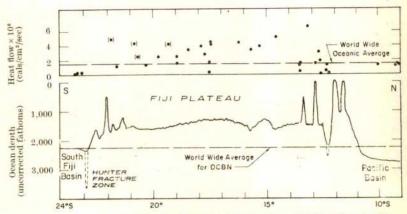

Fig. 2. A generalized profile of heat flow and bathymetry along 174° E. Stations showing a tilt of greater than 30° are in parentheses.

aries have extremely variable heat flow, both high and low, while, further to the north, the deep Pacific Basin has relatively constant normal values. The values shown on Fig. 1 in the latter area have a mean of 1.22 and a standard deviation of 0.29 µcal/cm²/sec. Fig. 2, a generalized profile of the heat flow and bathymetry along 174° E. and between 11° S. and 24° S., illustrates the striking

differences between the three regions.

The high mean heat flow through the plateau indicates unusually high temperatures at quite shallow depths. Although this high average value is similar to that through the Japan Sea, the Sea of Okhotsk and the Shikoku Basin⁸⁻¹⁰, the greater spread of values found on the Fiji Plateau may indicate a different origin. The Japan Sea has a uniformly high heat flow with almost all values lying between 1.7 and 2.5 µcal/cm²/sec. This high mean flow and low variance about the mean indicate a widespread region of anomalously high temperatures at shallow depths. On the other hand, the values found on the Fiji Plateau range widely. While the very high values surrounding Viti and Vanua Levu suggest a region of anomalously high temperatures beneath the islands, the high and low values found on the stations to the west indicate isolated igneous intrusions of recent origin.

Six out of twenty-five stations from R.V. Horizon yielded values of less than 0.3 μcal/cm²/sec. Such a high percentage of very low values is difficult to explain. Three of the values were found in the mountainous region north of the Plateau. The station at 12° 14' S. and 176° 11' E. on Fig. 1 with a bar over the value of 0.1 consisted of three separate penetrations of the probe. All three measurements gave the same overall temperature gradient. These stations were taken in a sediment trough adjacent to the island of Rotuma, so it is possible that the temperature gradient was disturbed by a recent sediment slump. The other two low values were also found in sediment troughs at the base of regions of high relief and consequently may have the same explanation. It seems a little unreasonable, however, to attribute so many low values to rapid sedimentation in a region which has been quiescent since the Miocene. The three low values just south of the Hunter Fracture Zone present a similar problem. The equivalent of a pebbly mudstone in the upper 30 cm of a gravity core, taken near the most easterly station, indicates a recent sediment slump which may account for the unusually low temperature gradient. It is possible that the low values found on the other two stations have a similar explanation. But the large distances (300 miles) between them and their position in the subdued topography, south of the sharp relief of the Hunter Fracture Zone, make such an explanation unlikely. On the other hand, Fig. 2 indicates that the regions of variable heat flow may be associated with the topographically rough northern and southern boundaries of the Plateau. This association of rough topography and mixed heat flow values is also found over the crest of the mid-ocean ridges and off the west coast of central America¹¹. It is possible that this association may be connected with the tectonic development of these regions.

The high mean heat flow of the North Fiji Plateau contrasts strongly with the uniform normal flow of the western Pacific basin. Three other regions which border the western flanks of the Pacific, the Sea of Okhotsk, the Japan Sea and the Shikoku Basin have a high average heat flow, though the values of the Shikoku Basin are more variable than those found in the other two seas (M. Langseth, private communication). The heat flow of these three marginal seas is also in strong contrast with the uniform normal flow of the western Pacific Basin. But the Japan Sea, the Sea of Okhotsk and the Shikoku Basin are all inland seas at a lower elevation than their surroundings, while the Fiji Plateau is a plateau which, although at the same depth as the marginal seas, is high in relation to the surrounding topography. This suggests

Relation, in the western Pacific, of high and normal heat flow ndesite line. ———, Andesite line (after MacDonald, 1949); hatched areas, known regions of high mean heat flow.

that on the western flanks of the Pacific there is a correlation between a given depth and high heat flow. On the other hand, this relationship may be purely coincidental. Fig. 3, which shows the distribution of known regions of high heat flow in the western Pacific, clearly illustrates that the island arcs, roughly traced by the andesite line, separate these regions from the Pacific Basin. A deep sea trench, large gravity anomalies, volcanoes and deep focus earthquakes are the features usually associated with island arcs. The distribution of the regions of high heat flow suggests that a high average heat flow in the marginal seas is another principal feature of the western Pacific island arcs.

The Nova Expedition is supported by the US National Science Foundation and the US Office of Naval Research. We would like to thank the captains, crew and scientists aboard R.V. Argo and R.V. Horizon for their co-operation during expedition Nova, and Mr F. Dixon and Mr J. Greenhouse for taking many of the heat flow measurements.

Pentameral Symmetry in **Echinoderms**

NICHOLS, in his recent restatements1,2 of the suture-line theory, has made out a strong case for the adaptive significance of pentameral symmetry in the newly metamorphosed echinoderm. Its admittedly transient advantages at this stage, however, do not seem to account for a pentamerous form persisting to determine the symmetry of the adult body. There are exceptions-Nichols1 quotes Promachocrinus—but why are they not the rule?

Nichols has looked for a reason for pentamerism in the life of modern echinoderms, but the evolution of echinoderms is a continuous process which has gone on since Pre-Cambrian times³. Once the pentameral condition had been established at some time in the past, in many members of the phylum it was likely to persist tenaciously in a variety of ways of life because any disadvantages of pentamerism are likely to be less than the disadvantages of changing it. Conversion of pentameral symmetry to a higher symmetry could not be done gradually because there is no intermediate between five-fold and six-fold radial symmetry. If it occurred as one mutation, the whole body-plan of the animal would be altered. groups in which parts of the skeleton fit together to form a rigid box, such as the theca of blastoids or the corona of echinoids, the disruption caused by this mutation would certainly be disadvantageous. In echinoids, with a corona of elaborate architecture and, in most groups, a complex jaw assembly also, the angular relationships and so the shapes of most parts of the skeleton would have to be altered to fit. This is presumably why the only echinoids without five rays are occasional teratological individuals. Where the constraint of a rigid test has been reduced, pentameral symmetry has been less persistent. In the asteroids, the basic skeletal structure is in the flexible arms. In consequence, the asteroids have both species (for example, Oreaster reticulatus4) and genera (for example, Luidia⁵) with pentameral and other symmetries. adaptability of the asteroid skeleton to this sort of disruption is illustrated in the growth of Pycnopodia helianthoides where the extra arms "wedge apart" the adambulacral and interbrachial ossicles as they develop.

Bather's theory' is an account of how the pentamerous condition may have arisen, and it is still favoured today. It may be possible to explain how the original trimerous condition arose in terms of the demands of bilateral symmetry, but, as Nichols^{1,2} points out, it is not clear why only the lateral rays divided, and those only once. Unless there is some constant, but unknown, ecological or anatomical factor involved, the failure of the anterior ray to divide must be explained by applying the suture-line theory to this stage in evolution. This would eliminate forms with an even number of rays produced by division of the anterior ray or only one lateral ray. Seven or nine rays, produced by a further division of the lateral rays, seem to have been unnecessary. It may be that five ambulacra carried sufficient podia for the early echinoderms, which tend to be smaller than their later relations. (This is better demonstrated from a collection of specimens than a collection of references.) Also, under the suture-line theory, seven or nine rays would make the animal more vulnerable. An echinoderm, which had evolved pentameral symmetry like this, might be capable of changing gradually in such ways as to give rise to all the major groups of echinoderms, without being able to attain a higher symmetry for the reason given in the second paragraph. Nevertheless, there seems to have been a need in many of the later groups for an increased number of podia, which has been met without losing the pentameral In Palaeozoic echinoids, the number of symmetry. ambulacral columns has been increased; in later echinoids, compound ambulacral plates have been developed10; in edrioasteroids, the ambulacra have become longer and

curved11; in crinoids the arms have frequently branched extensively12.

It would seem that a complete theory of echinoderm pentamerism should consider the history of these animals, especially in Cambrian and Pre-Cambrian times. Such a theory can be more firmly based as recently discovered fossils2,3 are further interpreted.

I am grateful to Dr David Nichols for reading a draft of this paper.

PHYSICS

Drag of Spheres in Dilute High **Polymer Solutions**

White showed that the drag on spheres in water, at Reynolds numbers exceeding the critical value (vd/v> about 2×10^5), could be increased by dissolving a very small quantity of polyethylene oxide (Union Carbide 'Polyox WSR301') in the water, and suggested that this effect resulted from suppression of turbulence in the boundary layer by the additive, which caused earlier separation and a corresponding increase in the wake size.

Experiments carried out below the critical Reynolds number, where the boundary layer is laminar, have shown that the drag on a sphere is considerably reduced by adding 'Polyox'²⁻⁴, although drag reduction in pipe flow occurs only in the turbulent regime. Flow visualization studies3 showed delayed boundary layer separation and a smaller wake size with the polymer solutions, which is consistent with the reduction of drag.

Tests have now been carried out for a wider range of Reynolds number to span the critical region; the technique of measurement was similar to that of the previous investigators. Steel spheres were dropped down through cylinders containing the test liquid; the spheres were

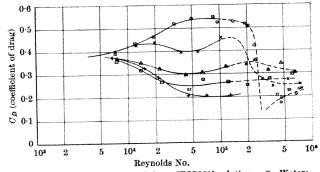

Fig. 1. Drag of spheres in 'Polyox WSR301' solution. ○, Water; ×, 10 p.p.m. 'Polyox' solution; △, 30 p.p.m. 'Polyox' solution; □, 60 p.p.m. 'Polyox' solution; +, 120 p.p.m. 'Polyox' solution.

released from a point just below the surface of the liquid by an electro-magnet. The apparatus was kept in a darkened room and for each test the falling sphere was illuminated by a strobo-flash unit operating at mains frequency (50 c/s). Measurements from multiple image photographs on high speed 'Polaroid' film enabled the terminal velocities to be determined, from which the corresponding drag coefficients were calculated.

Two rigs were used: spheres between 0.25 in. and 1.5 in. in diameter were dropped into a 'Perspex' tube 10 ft. high by 6 in. in diameter, and the larger spheres ranging in diameter from 1.5 in. to 4.5 in. were dropped into a steel vessel 22 ft. high by 2 ft. in diameter which had 'Perspex' windows near the bottom for observation purposes. The spheres frequently deviated from a vertical path during their descent and struck the sides of the containers, and in all such cases the results were discarded.

The results obtained with water and dilute 'Polyox' solutions are shown in Fig. 1. The drag coefficients at low values of Reynolds number agree to a large extent with the results of previous investigators. It can be seen that at high Reynolds numbers adding polymer increases the drag, as the preliminary experiments suggested. Small increases in viscosity have been taken into account in evaluating the Reynolds numbers because these very dilute solutions seem to be Newtonian under steady laminar capillary flow. Results obtained in the large rig are shown connected by dashed lines. Tests have also been carried out with equimolar solutions of cetyltrimethylammonium bromide (CTAB) and 1-naphthol. This complex soap system was previously found to exhibit very large drag reductions in turbulent flow in pipes, although the effect terminated when the shear stress of the wall exceeded a certain value, probably because of changes in or disruption of the micelle structure. This could account for the reduced effectiveness in drag reduction at higher values of Reynolds number as seen in Fig. 2. The highest concentration was found to be slightly pseudoplastic at low shear rates with a flow index, n, of about 0.9, and because possible structure changes at high shear rates make viscosity difficult to interpret, the Reynolds numbers of Fig. 2 have been based on the viscosity of water.

Sphere drop tests in a 500 p.p.m. solution of guar gum exhibited no significant reduction in drag although similar solutions in pipe flow produce a large decrease in flow resistance6

Bizzell and Slattery' predicted that for a power law fluid the separation point would move towards the rear of the sphere as the flow index, n, decreased, but all the solutions used in this investigation were Newtonian under steady laminar capillary flow (n=1), except for the highest concentration of the soap system. Gadd's has shown that freshly mixed solutions of 'Polyox' exhibit normal stress differences in shear flow, while this effect is not found with dilute guar gum solutions. Normal stress measurements have not yet been carried out with the

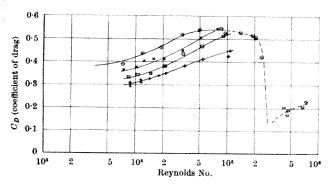

Fig. 2. Drag of spheres in equimolar solutions of cetyltrimethylammon-lum bromide (CTAB) and 1-naphthol. \bigcirc , Water; \times , 264 p.p.m. total concentration; \square , 508 p.p.m. total concentration; +, 1,016 p.p.m. total concentration.

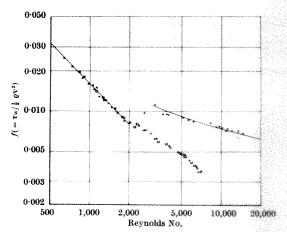

Fig. 3. Comparison of fresh and aged 'Polyox' solutions in pipe flow. (Pipe diameter, 0-090 in.) ♠, Water; ×, 30 p.p.m. 'Polyox' solution (fresh); ○, 30 p.p.m. 'Polyox' solution (aged for 6 days).

soap systems, which are certainly visco-elastic as the erratic rise of air bubbles through the solutions shows.

Brennen and Gadd' have found that the elastic effects with a dilute 'Polyox' solution disappear after agoing for several days, although the reduction of skin friction remains unchanged. The results shown in Figs. 1 and 2 were obtained with freshly mixed solutions; the effect of ageing on the drag of a sphere in 'Polyox' solution is illustrated in Table 1.

Table 1. SPHERE DIAMETER 0.5 IN.

Age (days)	C_{B}
Fresh	0.324
1	0.346
2	0.362
3	0.390
6	0.443

Cp in water was 0.475, and 30 p.p.m. of 'Polyox WSR301' was used.

After 6 days the sphere drag reduction virtually disappeared. Pipe friction measurements were then carried out with this same aged solution and also with a freshly mixed solution at the same concentration. Fig. 3 shows that the increasing drag on a sphere with age cannot be ascribed to degradation, because practically identical pipe friction results were obtained with the fresh and aged solutions.

These results then seem to indicate that the delayed laminar separation is caused by visco-elastic effects. because the phenomenon seems to occur only with solutions which exhibit normal stress difference behaviour. It is possible that the stress system set up in the shear flow within the boundary layer tends to strangulate the fluid onto the sphere in a way somewhat similar to the Weissenberg effect with flow in an annulus with an outer rotating cylinder.

I thank the Hoffmann Manufacturing Company Ltd., Chelmsford, for providing a wide range of precision steel balls used in this investigation.

Absolute Experimental and Theoretical Determination of the Copper-63(n,2n)Copper-62 Reaction Cross-section

The copper-63(n,2n) copper-62 reaction cross-section has been accepted1 as a standard for measuring neutron flux in the 14 MeV region. Unfortunately, this crosssection varies rapidly with neutron energy, and thus it is important that the cross-section should be predictable on a theoretical basis in order to relate the various experimental determinations. Usually 2,3 (n,2n) cross-sections are calculated on the statistical model using an experimental value for the relevant (n,n) cross-section. In this investigation the necessity of the measured (n,n) crosssection has been eliminated.

After Vandenbosch and Huizenga⁴, the cross-section $\sigma(J_c)$ for forming any angular momentum state J_c in the compound nucleus is given by

$$\sigma(J_c) = \pi \left(\frac{\lambda}{2\pi}\right)^2 \frac{\sum\limits_{S=|I-s|}^{I+s} \frac{J_c+S}{\sum\limits_{I=|J_c-S|} (2I+1) (2s+1)} \frac{(2J_c+1)}{(2s+1)} T_l(E) (1)$$

where I is the spin of the target nucleus, s is the spin and the angular momentum of the incident particle, and $T_l(E)$ is the barrier penetration coefficient for a given l and incident neutron energy, E. The total cross-section σ_{end} for the compound nucleus formation is obtained by summing over the available J_c values. The compound nucleus can then decay by the various particles evaporating into different final nuclei.

The (n,2n) cross-section, $\sigma(n,2n)$, is given by

$$\sigma(n,2n) = \sigma_{cpd} \frac{P(2n)}{\Sigma P(x)}$$
 (2)

where P(2n) is the probability of evaporating two neutrons, P(x) is the probability of evaporating any particle x, and $\Sigma P(x)$ is the total probability of decay of the compound nucleus.

Vandenbosch and Huizenga⁴ give the cross-section for forming a spin state J_F in the final nucleus, $P(J_F)$, as

$$P(J_F) \propto (J_c) \
ho(E) \ rac{(2J_F+1)}{2\sigma^2}$$

$$\exp\left(-(J_F + \frac{1}{2})^2/2\sigma^2\right) \sum_{S=|J_C - S|}^{|J_F|S|} \sum_{l=|J_F - S|}^{|J_F|S|} T_l(\varepsilon)$$
 (3)

Where $T_l(\varepsilon)$ is now the barrier penetration coefficient for a particle X leaving the compound nucleus with excitation energy ε . Here s is the spin of the emitted particle X. The probability, P(x), of any given particle x being emitted is assumed to be proportional to the sum of the $P(J_F)$ values over the available J_F states.

Expression (3) refers to the emission of a single particle from the compound nucleus and is not immediately useful for the emission of two neutrons. Okumura⁵ approaches the problem of the second emitted neutron by neglecting the angular momentum changes caused by this emission. In this investigation the calculation is performed by first using expression (3) to calculate angular momentum distribution caused by the emission of one neutron and then repeating the calculation for the second neutron.

The value of σ , the spin cut-off parameter, was taken to be 4.0, in accordance with the large amount of experimental evidence published on this parameter in work on isomeric cross-section ratios for nuclei of mass number near 60 (refs. 6-9). It should be pointed out, however, that the effect of changes of ± 1 in this parameter will cause little change in the final value for the (n,2n) crosssection because its function is to prevent the distribution of angular momentum in the final nucleus reaching high values. This is the case for both P(2n) and $\Sigma P(x)$.

The value of $\rho(E)$, the level density in the final nucleus for zero spin, is taken to be

$$ho(E) \propto \mathrm{e}^{2\sqrt{Ea}}$$

where E is the excitation of the final nucleus, and a is the level density parameter, taken to be 2 MeV-1 after Blatt and Weisskopf¹⁰ and also in accordance with the method used by Chatterjee¹¹ using the Weisskopf-Ewing

For an incident neutron energy of 14.7 MeV, the copper-63(n,2n)copper-62 cross-section is given by this calculation to be 582 millibarns which is in good agreement with the experimental measurements made in this laboratory; namely, 594 ± 26 millibarns for incident neutrons of energy 14.7 ± 0.2 MeV. Pasquerelli¹² reports a lower experimental value of 511±15 millibarns for a neutron energy of 14.7 ± 0.1 MeV, and Grimeland obtained values of 568 ± 16 millibarns and 548 ± 10 millibarns for 14.8 ± 0.1 MeV neutrons.

In this laboratory the neutrons were obtained from the T(dn)He4 reaction using an incident deuteron energy of 140 keV. The neutron yield was measured by the associated particle technique, detecting alpha particles at 150° to the deuteron beam using a silicon surface barrier detector. The variation in yield with time was recorded and integrated both numerically and by an electrical analogue method. In order to relate the alpha and neutron yield an isotropy correction appropriate to thick target neutron production was applied.

Copper disk samples were positively located close to the back of the tritium titanium target and received neutrons emitted over a cone of solid angle 0.66π steradians. The effect of the finite source size and non-uniformity was determined theoretically¹⁴. This gave an uncertainty in the estimation of the neutron flux at the copper sample

of ± 2.9 per cent.

The induced activity of the samples was determined from the photopeak of the annihilation radiation, detected using a 3 in. x3 in. NaI (Tl) scintillation spectrometer; the annihilation radiation source being localized by placing the copper samples in an aluminium converter positioned 10 cm from the crystal. The efficiency of the crystal was taken from the theoretical works of Heath¹⁵ and Grosjean¹⁶, and was cross-checked with a standard sodium-22 source using the 1-28 MeV photopeak. The peak to total ratio of the crystal was determined experimentally and the accuracy of the counting equipment was estimated to be 3.1 per cent.

The overall accuracy of the measurement, which included the statistical errors and uncertainties caused by the source and sample positions, was obtained by combining the errors quadratically, and was estimated to be $4 \cdot 3(4)$ per cent.

The theoretical variation of the cross-section with neutron energy is also in close agreement with preliminary experimental results over the range 14 MeV to 15 MeV. This substantiates the value of a as 2 MeV⁻¹ as being the correct one. In addition, the calculation has proved capable of enabling a prediction of the value of the copper-65(n,2n)copper-64 cross-section which was computed to be 890 millibarns at 14.7 MeV in close agreement with the value obtained experimentally in this laboratory of 968 ± 68 millibarns at 14.7 ± 0.2 MeV.

We thank Professor S. E. Hunt, Dr P. N. Cooper and Dr P. E. François for their help and encouragement.

MOLECULAR STRUCTURE

Solid "Liquid Crystal" Films of Poly-Y-benzyl-L-glutamate

WE present here evidence for a planar layered structure in solid films of poly- γ -benzyl-L-glutamate (PBG) made by casting from solution. The (idealized) structure is composed of successive layers of planes parallel to the film surface. The planes themselves consist of "domain' regions of parallel helical molecules. In a given domain the molecules in adjacent planes show a slight angle of twist relative to one another, characteristic of cholesteric liquid crystal structures. An interesting manifestation of this suggested structure is the unusually anisotropic swelling of these films. Films plasticized with a nonvolatile solvent also maintain this layered cholesteric structure with a uniform separation of the PBG planes as shown by birefringence studies.

The structure of reasonably concentrated solutions of PBG has already been extensively characterized¹⁻⁵ and these solutions, which were in a fluid condition in contrast to our solid films, were shown to have a cholesteric liquid crystal structure. Close to the container surface, the molecular planes were parallel to the surface. Within the fluid, however, the molecular planes of the cybotactic regions were isotropically arranged.

The structure of the solid films (unplasticized and plasticized) which are discussed here was inferred from (a) swelling studies, (b) birefringence studies, and (c) X-ray observations6.

Films of PBG of high molecular weight (Pilot Chemicals; molecular weight, 105) 0.1 cm thick were prepared by slow evaporation of chloroform solutions. Solutions with initial concentrations of approximately 10 per cent PBG were contained in cylindrical polyethylene rings placed on a mercury surface. Homogeneous films plasticized with 'Aroclor' (chlorinated polyphenyls) were prepared by similar casting of predetermined ratios of 'Aroclor' and PBG dissolved in chloroform, then evaporating the chloroform.

The mechanical properties of these films are dependent on the concentration of plasticizer. The room temperature torsional modulus, G, measured after 10 sec, is shown in Table 1.

The PBG molecule has been shown to retain its α -helical conformation in the solid state, and oriented plasticized films (20 per cent PBG) also exhibit the characteristic infrared dichroism associated with a helical molecular conformation.

When the completely dried films (100 per cent PBG) were introduced into benzene immediate anisotropic swelling of the films was observed. The film shape was retained

T	able 1
Per cent PBG	3G (dynes/cm ³
100	5 × 10°
60	2.3×10^{s}
50	1.2×10^{9}
30	2×10^{8}
20	3.5×10^7

and dimensions of apparent equilibrium were attained within several minutes. There was a 400 per cent increase in the thickness of the film in a direction N normal to the surface of the film while the other dimensions (parallel to the film surface) increased about 20 per cent. The film remained in a solid condition and could be handled without change of shape.

Plasticized films also showed the same anisotropic swelling in benzene. The swelling was reversible, and the film approached its original dimensions as the solvent

evaporated.

The structure of the swollen film was studied in further A thin section detail with a polarizing microscope. $(2-3\mu)$ was cut perpendicular to the surface of a 100 per cent PBG film and swollen in benzene as described. Between crossed polars, the direction of viewing was in the plane of the original film. In the swollen condition, regularly spaced retardation lines were seen parallel to the surface of the film (and perpendicular to N_L maximum swelling the spacing S between retardation lines was about 2u

In concentrated fluid solutions of PBG, the existence of retardation lines was regarded as very strong evidence for the liquid crystalline (cholesteric) structure 1-5. Robinson also gave a relation between the spacing S and the concentration of PBG in solution². We find the relation to be approximately valid for our swollen (but solid) film.

It is possible that retardation lines on the 100 per cent PBG film (unswellen) cannot be resolved under a microscope because the value of S is smaller than the wavelength of visible light, and this may be why they were not observed by Elliott and Ambrose¹. The retardation lines can, however, be observed in films sufficiently plasticized with 'Aroclor', just as they can in films swollen in

The structure of solid films of PBG east from chloroform solutions has also been examined by X-ray measurements in this laboratory. This structure was tentatively interpreted in terms of co-existing paracrystalline and mesomorphic regions with uniplanar orientation of the molecules in the plane of the film⁶. The new results reported here support this interpretation.

Films (100 per cent PBG) moderately crosslinked in the solid state by gamma irradiation also showed anisotropic swelling, which indicates the preservation of anisotropic order in the crosslinked solid. Perhaps the crosslinks form preferably in the parallel planes. The plasticized films can be readily handled in their original form but may also be crosslinked to lock in permanently the cholesteric structure.

Denaturation Kinetics of Biopolymers by Differential Thermal Analysis

Several workers have described equations to calculate the activation energy of a reaction from the exothermic or endothermic peaks which occur during a differential thermal analysis (DTA) experiment¹⁻². There is a second type of differential thermal analysis curve, one not

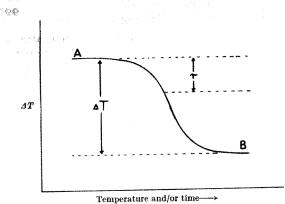

Fig. 1. Idealized sigmoid type thermogram; explanation in text.

characterized by a maximum or a minimum but by a sigmoid shape caused by a change in the heat capacity of the system during the experiment. Fig. 1 shows an idealized sigmoid type isotherm. Such curves are well known in polymer chemistry, where they indicate the occurrence of a so-called second order phase transition in the solid polymer. We report here the observation of such thermograms for aqueous solutions of several biopolymers including proteins and nucleic acid, and direct attention to the possibility of obtaining kinetic data from them.

It can easily be shown that if A represents the state of the system along the upper baseline of Fig. 1 and B represents a second state along the lower baseline, then the degree of conversion of A to B at any time is given by

$$\alpha = \frac{\tau}{\Delta T} \tag{1}$$

where ΔT is the total displacement of A from B and τ the displacement at time t. The extent of the reaction at any time t after the start may be expressed by

$$\int_{\frac{1}{\sqrt{1-\alpha}}}^{a} \frac{\mathrm{d}\alpha}{(1-\alpha)^n} = At \exp\left(-\frac{E}{RT}\right)$$
 (2)

where E is the activation energy for the process, A is a constant, R the gas constant, T the temperature and nthe order of the reaction. If the reaction involves only a change in heat capacity, then its activation energy can be obtained from equation (2) by a plot of

$$\ln \left[\frac{1}{t} \int \frac{\mathrm{d}\alpha}{(1-\alpha)^n} \right] \text{ against } 1/T$$

Our data for the thermal denaturation of pepsin and ovalbumin gave linear plots for n=1 and yielded values for the activation energies slightly lower than those published. Thus we find 39 kcal/mole for 0.5 per cent pepsin for which Casey and Laidler4 report 56 kcal/mole, and 79 kcal/mole for 0·1 per cent ovalbumin where Lewis⁵

reports 132 kcal/mol.

There are several possible reasons for this discrepancy. Undoubtedly one factor involves our need, at present, to work with unbuffered systems. This is necessitated by the effect of temperature on the ionization of the buffer; the resulting enthalpy changes swamp out the changes in heat capacity caused by the denaturation process. It is also possible that the biochemical criterion for heat denaturation measures a slighty different process from that detectable by differential thermal analysis. Furthermore, Casey and Laidler4 report an activation energy for the initial rate of reaction while the differential thermal analysis experiment gives an average for the temperature range of the transition. The same workers also reported that the activation energy increases as the concentration of the solution decreases, a factor which could account for

the discrepancy between our value for ovalbumin and that of Lewis.

Similar experiments performed on gels of calf thymus DNA also produced sigmoid type thermograms in the temperature range of 60°-80° C. A wide variety of experiments by other workers have shown that DNA undergoes a helix-coil transition in this temperature range. Calculation of the activation energy for the process measured by the differential thermal analysis experiment gave a linear plot for n=1, corresponding to E=30.0 kcal/mole.

It is apparent that the differential thermal analysis experiment provides a valuable insight into structural changes occurring in solutions of biopolymers such as proteins and nucleic acids.

CHEMISTRY

Formation of Metastable Atoms of Phosphorus, Arsenic and Antimony by Flash Photolysis

ELECTRONICALLY excited atoms (${}^{2}D^{0}, {}^{2}P^{0}$) of phosphorus, arsenic and antimony have been observed in absorption after isothermal flash photolysis of phosphine, arsine and stibine. These metastable atoms were also observed with phosphorus trichloride and tribromide, arsenic trichloride and tribromide, and antimony trichloride. So far, nine atomic lines of phosphorus, eight of arsenic and forty-four of antimony have been identified, arising from the excited states, and two transitions involving the ground state (${}^4S^6$) of antimony have also been observed. The states involved and the transitions observed are listed in Table 1. Several of the transitions were also observed in emission and these are indicated by an asterisk in Table 1.

Vibrationally excited P2, As2 and Sb2 were also observed with the exception that no Sb₂ was produced from

antimony trichloride.

Arsine and stibine were prepared according to Gunn et al.1. Phosphine (Matheson), phosphorus trichloride, phosphorus bromide and arsenic trichloride (Baker and Adamson), arsenic tribromide (K and K) and antimony trichloride (May and Baker) were purified by distillation Pressures used for these compounds were usually in the range 0.5-0.1 mm of mercury, although as low as 10-4 mm of mercury was used for antimony. The compound, with a large excess (about 250 mm of mercury) of nitrogen added, was flash photolysed at an energy of about 1,000 Joules in a 50 cm long reaction vessel. The spectra were recorded on Ilford HP3 plate using a Hilger quartz spectrograph, model E742.

The production of PH2 and PH and of vibrationally excited P2 in the flash photolysis of phosphine has been explained by the mechanism²

$$PH_3 + h\nu \rightarrow PH_2 + H \tag{1}$$

$$H + PH_3 \rightarrow H_2 + PH_2$$
 (2)

$$2PH_2 \rightarrow PH_3 + PH \tag{3}$$

$$2PH \rightarrow P_2 * + H_2 \tag{4}$$

The reaction

$$H + PH_2 \rightarrow H_2 + PH$$
 (5

was considered less likely. The same mechanism can be applied to the flash photolysis of NH₂ (ref. 3) and it seems likely that similar reactions occur for all the compounds studied. The observation of the spectra of AsH2 and AsH (refs. 4 and 5), SbH₂ and SbH (ref. 5), NCl₂ and NCl (ref. 6) and of PCl (ref. 7), AsCl (unpublished work) and SbCl (ref. 5) in the flash photolysis of the appropriate hydride or halide is consistent with this The vibrationally excited P₂ which we observe with phosphorus trichloride and phosphorus tribromide as well as with phosphine could arise from reactions similar to equation (4) and the same applies to the production of vibrationally excited As, from arsine and the arsenic halides. That excited Sb₂ is produced from stibine, while no Sb₂ was observed with SbCl₃, is in accord with the probable endothermicity of the corresponding reaction for SbCl.

The production of ground state (4S0) atoms can readily be explained by a logical extension of the mechanism. Representing the phosphorus, arsenic or antimony atoms by A and the chlorine or bromine atom by X, the nineteen reactions possible for the compounds studied are summarized by the equations

$$AH + H(AH,AH_2) \rightarrow A + H_2(AH_2,AH_3)$$
 (6)

$$AX + AX(AX_2) \rightarrow A + AX_2(AX_3) \tag{7}$$

The three reactions involving hydrogen atoms are sufficiently exothermic to produce $A(^{2}D^{0})$, but to account for the presence of excited atoms in all systems, the AX or AX_2 radicals (and perhaps AH or AH_2 also) must be vibrationally or electronically excited.

Calculation shows that a sufficient concentration of the vibrationally excited radical could probably be produced by termolecular recombination. Reactions (6) and (7) then follow with the additional possibility, in some cases, of atom excitation by energy transfer from these (or other) excited species.

Alternatively, excited AX(AH) and $AX_2(AH_2)$ radicals could be produced by primary or secondary photolysis:

$$AX_3(AH_3) + hy \rightarrow AX_2^*(AH_2^*) + X(H)$$
 (8)

$$AX_3(AH_3) + h\nu \rightarrow AX^*(AH^*) + X_2(H_2)$$
 (9)

$$AX_2(AH_2) + hv \rightarrow AX^*(AH^*) + X(H)$$
 (10)

A logical extension of this approach is the direct production of excited atoms by secondary photolysis:

$$AX_2(AH_2) + hy \rightarrow A^* + X_2(H_2)$$
 (11)

$$AX(AH) + hv \rightarrow A* + X(H)$$
 (12)

Whichever mechanism is adopted, it seems probable that the initial production of atoms in only one of the two excited states observed need be accounted for, because interconversion by secondary absorption is possible.

$$A(^{2}D^{0}) \xrightarrow{h_{\nu}} A(^{2}P) \xrightarrow{M,-h_{\nu}} A(^{2}P^{0})$$
 (13)

Evidence that these processes occur is provided by the fluorescence we observe from the 2P state to both metastable states.

Until the mechanism of production of excited atoms is understood more fully and the concentrations of atoms in all three electronic states are measured, the extent to which the mechanisms for the flash photolysis of the compounds AH_3 and AX_3 need to be modified remains uncertain. This work is being continued and will be extended into the vacuum ultraviolet for studies on ammonia and on ground state phosphorus and arsenic atoms.

We thank the National Research Council of Canada for a research grant.

Lewis Base Adducts of Cobalt and Iron Bis-1,2-dithiolenes

TREATMENT of the dimeric dianionic iron and cobalt dithiolenes, $[MS_4C_4R_4]_1^2$, $[Fe(S_2C_6H_3Me)_3]_1^2$ and $[Fe(S_2C_6C_4)_2]_1^2$, where R is CN, or CF₃, with Lewis bases such as pyridines, phosphines, stibines, CN- or N₃-, results in the dissociation of the dimers and formation of five co-ordinate adducts, $[M(L)-S_4]^{-1}$ or $[M(L')-S_4]^{-k}$, where L is a neutral and L' is a monoanionic Lewis base. With bidentate bases such as a, a'-dipyridyl and o-phenanthroline, six-co-ordinate complexes, $[M(N-N)-S_4]^{-1}$, were formed, and similar adducts of the cobalt dithiolenes with ethylenediamine and dimethylglyoxime were also prepared.

Similar dissociative behaviour and adduct formation had been observed1,2 in the reactions of nitric oxide with these dimeric iron and cobalt dithiolenes, and the fiveco-ordinate nitrosyls had been observed to undergo facile one-electron transfer reactions. A voltammetric study of these new Lewis base adducts in dichloromethane established that they, too, could undergo one-electron transfer reactions. Thus almost all the complexes studied (some species were labile in solution, thus precluding an investigation of their voltammetric behaviour) displayed reversible voltammetric waves corresponding to the generation of neutral and dianionic species, and many also exhibited waves corresponding to monocations being formed (Table 1). It seems therefore that, in these adducts of two- and four-electron donors, a four-membered electron-transfer series can be envisaged, that is

$$\begin{array}{l} [M(L)-\mathbf{S}_4]^{-2} {\longleftrightarrow} [M(L)-\mathbf{S}_4]^{-1} {\longleftrightarrow} [M(L)-\mathbf{S}_4]^{0} {\longleftrightarrow} M(L)-\mathbf{S}_4]^{+1}, \\ [M(\mathbf{N}-\mathbf{N})-\mathbf{S}_4]^{-2} {\longleftrightarrow} [M(\mathbf{N}-\mathbf{N})-\mathbf{S}_4]^{-1} {\longleftrightarrow} [M(\mathbf{N}-\mathbf{N})-\mathbf{S}_4]^{0} {\longleftrightarrow} \\ [M(\mathbf{N}-\mathbf{N})-\mathbf{S}_4]^{+1} \end{array}$$

The limited amount of voltammetric data available suggests that the half-wave potentials for these redox reactions depend on four factors: the central metal atom; the nature of the sulphur ligand (that is, its substituents); the nature of the adduct donor atom; and the donor atom substituents. The dependence of half-wave potentials on the sulphur ligand substituents and metal atom has already been observed in other dithiolene systems1-5 and it is recognized that the electron-releasing ligands tend to stabilize the more oxidized members of an electron transfer system. A similar effect seems to be exerted by the adduct donor atoms and their substituents, but a more extensive study is necessary before the precise effects of the donors can be assessed.

The five-co-ordinate iron monoanions, $[Fe(L)-S_4]^{-1}$, and [Fe(N₃)-S₄]-2, containing weak-field ligands, were highspin $(\tilde{S}=3/2)$ and had magnetic moments at room temperature consistent with three unpaired electrons. This observation indicates that the so-called anomalous magnetic behaviour of the simple iron dithiolenes in donor solvents6 is probably caused by the dissociation of the low-spin dimers (S=1/2) into high-spin monomers which may be complexed by one molecule of solvent. The fiveco-ordinate iron monoanions, and [Fe(CN)-S₄]-2, which contain strong-field ligands, are low-spin (S=1/2), as are the six-co-ordinate iron complexes. All of the cobalt adducts are diamagnetic.

The adducts with spin-doublet ground states exhibited electron spin resonance signals in solution at room temperature (Table 1). Thus the monoanionic phosphine

complexes, [Fe(PR₃)-S₄]-1, displayed doublet signals due to phosphorus-31 nuclear hyperfine coupling, and had g-values and hyperfine splittings averaging 2.045 and 28.0 gauss, respectively. These data are in direct contrast to those obtained from the formally isoelectronic cobalt complexes $[Co(PR_3)S_4C_4Ph_4]^6$ (ref. 7) where cobalt-59, but not phosphorus-31, hyperfine splittings were detected; an exception to this occurred in [Co(P(OPh)₃)S₄C₄Ph₄]⁰ where a small phosphorus-31 coupling (about 8.5 gauss) was resolved. The g-values and metal hyperfine splittings in these neutral cobalt complexes averaged 2.017 and 24.6 gauss, respectively. The dipyridyl and o-phenanthroline adducts $[Fe(N-N)-S_4]^{-1}$, and $[Fe(CN)-S_4]^{-2}$, displayed broad electron spin resonance signals and no nitrogen-14 or carbon-13 hyperfine structure was detected. The width and resolution of some of the resonance signals detected in solutions containing the phosphine adducts and CNwere found to be temperature dependent. A detailed study of the magnetic properties of these adducts and of their electronic structure is in progress.

Preliminary Study of Variations of Oxygen and Sulphur Isotope in Natural Sulphates

WE have recently developed a method for studying variations in oxygen-18 and sulphur-34 in sulphates using the same specimen for the preparation of carbon dioxide and sulphur dioxide for mass spectrometry.

One of us¹ described in detail a method for the extraction of oxygen from sulphates for studying their oxygen isotope ratio, and showed that some normal chemical procedures for the recovery of sulphates could bring about changes in the original oxygen isotope ratio. We² studied these changes in greater detail, and developed a satisfactory method for the recovery of sulphates from a variety of natural sources. Sulphates can be recovered, purified and reduced by graphite for conversion of the oxygen to carbon dioxide for mass spectrometer measurement of the ratio of the oxygen-18 to oxygen-16. The procedures described cause no changes in the original ratio. The recovery of the oxygen from the sulphate is 98-99 per cent and reproducibility of the method is ± 0.18 p.p.t. The sulphur is recovered for measurements of the ratio of sulphur-34 to sulphur-32 as described earlier³.

Longinelli and Craig4 described a method similar to ours for the study of oxygen-18 variations in sea water and saline lakes. They also reported δ oxygen-18 values for sulphates and water with respect to standard mean ocean water (SMOW). The conventional method for reporting measurements of oxygen isotope abundance in carbon dioxide is as parts per thousand with respect to carbon dioxide liberated from PDB Chicago Limestone Standard

by reaction with ortho-phosphoric acid and then expressing these results with respect to SMOW, using the relationship

$$\delta^{18} O_{sample} = 1.0409$$
 $\delta^{18} O_{sample} + 40.92 \text{ p.p.t.}$
with respect with respect to SMOW to PDB

 δ is the deviation in parts per thousand of the oxygen-18 to oxygen-16 ratio from that in the standard, where

$$\delta \ {\rm oxygen\text{-}18 \ p.p.t.} = \frac{{}^{18}{\rm O}/{}^{16}{\rm O}_{\rm sample} - {}^{18}{\rm O}/{}^{16}{\rm O}_{\rm standard}}{{}^{16}{\rm O}/{}^{16}{\rm O}_{\rm standard}} \times \frac{1000}{1}$$

An immediate comparison between the results of Longinelli and Craig and the results from this laboratory was possible. Longinelli and Craig showed that sulphate ions in sea water and saline lakes were enriched in oxygen-18 by between 7 and 23 p.p.t. relative to SMOW. We have studied oxygen-18 enrichment in sulphates from several sources and attempted to show correlations between sulphate oxygen and the water in which the sulphate existed and between the oxygen and sulphur isotope variations in the sulphate ions themselves. Results are shown in Figs. 1 and 2.

Longinelli and Craig found that the sulphate ions in the ocean were enriched in oxygen-18 by 9·5 p.p.t. relative to SMOW. We have measured the δ oxygen-18 values in six coastal sea waters and eleven samples from an ocean profile to a depth of 2,500 m collected around New Zealand. These seventeen samples gave an average of 9·9 p.p.t., so there is little difference between δ oxygen-18 values in sulphates from sea water measured in our laboratory and those of Longinelli and Craig. There was no isotopic temperature correlation between the sulphate and water oxygens in sea water, which supports the known stability of the sulphate oxygens which have been shown to exchange extremely slowly⁵.

An interesting series of sulphate and water samples from Lake Vanda, Antarctica, were available. It was known that these samples came from layers of strongly density-stratified non-connective saline waters in the temperature range 19·4°-25·5° C (ref. 6).

As we reported, between depths of 180 and 215 ft. the δ sulphur-34 values varied progressively from +20 to +39.4 p.p.t. with respect to meteoritic sulphur. The δ oxygen-18 values in these sulphates gradually increased from -9.4 to -3.6 p.p.t. with respect to SMOW, while the saline water oxygen increased from -31.2 to -28.9 p.p.t. with respect to SMOW. Antarctic snow water in this area has a δ oxygen-18 value of -30 p.p.t. with respect to SMOW. Assuming equilibrium conditions to have been established, we calculated the isotopic equi-

librium temperatures of around -20° C from the oxygen isotopic data. This temperature does not correlate with the present water temperatures but with the mean air annual temperature (-20° C) for this region. As shown in Fig. 1, the δ oxygen-18 and δ sulphur-34 values of the sulphate steadily increase with depth. We can speculate that the oxygen-18 variation has taken place at the same time as the sulphur-34 variation, although we cannot explain at present how such oxygen-18 and sulphur-34 variations have occurred. These samples also show a clear correlation between oxygen-18 variations of sulphate ions and associated water (Fig. 2). This may represent some interaction of sulphate ions with the water, but we cannot at present explain this because we do not know the origin of the sulphates. The δ oxygen-18 values in the water and sulphate above the non-convective layers will be studied when Lake Vanda can be sampled again.

Because the sulphur isotope variations in the sulphate and hydrogen sulphide, from geothermal bore waters at Wairakei, New Zealand, had already been studied, we decided to examine the oxygen-18 variations in the sulphates and water from these bores. It was observed that while the δ sulphur-34 values for the sulphates were very similar to those in sea water sulphates (approximately +20 p.p.t. with respect to meteoritic sulphur), the δ oxygen-18 values for the sulphate oxygen were very close to those of SMOW (not approximately 10 p.p.t. heavier as is the 8 oxygen-18 value for sea water sulphate). The δ oxygen-18 value for geothermal bore-water was found to be approximately -5 p.p.t. with respect to SMOW. From these results, assuming equilibrium conditions, we calculated the isotopic equilibrium temperature in the bores to be about 140° C, while the measured temperature is around 270° C. It seems likely that the high temperature of this geothermal water produces isotopic equilibrium between the sulphate ions and the water, and so we think it possible that the isotopic equilibrium temperature obtained is too low because of uncertainties in the theoretical isotopic equilibrium constants calculated by Urey⁸.

The ratio of oxygen-18 to oxygen-16 has also been measured in a number of rain water sulphates. It was found that their δ oxygen-18 values (approximately +11 p.p.t.) were 1-3 p.p.t. heavier than sea water sulphate oxygen.

We know from our investigation of sulphur isotope that the sulphate in rain water does not come principally from sea water spray. Rain water in this area has a δ oxygen-18 value of -6 p.p.t. with respect to SMOW and in the evaporation procedure for recovery of the sulphate this increases to +25 p.p.t. If the sulphate oxygens are as

stable as reported, this evaporation procedure should not change the δ oxygen-18 value. This is now being tested using sulphates of known oxygen-18 to oxygen-16 ratio. Atmospheric oxygen has a δ oxygen-18 value of +22.73p.p.t. (ref. 10). Tests are being run to determine the isotopic fractionation which may take place if rain water sulphate is formed by the atmospheric oxidation of hydrogen sulphide, to explain our δ oxygen-18 values for rain water sulphates.

To evaluate further the spread in δ oxygen-18 values in nature, thirty-seven barite specimens were examined. Their oxygen-18 values covered the range 7.8 to 25.5 p.p.t. relative to SMOW. Small variations within different barite deposits were observed, but distinct variations existed between different mining areas. Secondary barites were clearly different from primary barites in δ oxygen-18 values. Remarkable enrichments in oxygen-18 and sulphur-34 as large as +25.5 p.p.t. with respect to SMOW and +57.9 p.p.t. with respect to meteoritic sulphur, respectively, were found in diagenetic barite (from upper cretaceous concretions, Kaipara, New Zealand, collected by W. H. Hodgson, University of Otago) associated with calcite. These enrichments may represent effects of bacterial reduction of either sulphates or interaction of the barite with the calcite or both. Good specimens of co-existing sulphate-oxide minerals have yet to be examined to test the usefulness of this method in palaeotemperature studies.

In this paper we have found some clear correlations between oxygen-18 and sulphur-34 variations both within and between each different type of sulphate, as shown in Fig. 1, and between oxygen-18 in sulphate and its associated water, as shown in Fig. 2. The extent to which biological, chemical and physical processes are involved in such distribution requires further detailed studies of all the factors involved.

We thank M. K. Stewart for oxygen ratio measurements in waters and D. W. N. Keith for sulphur isotope measure-One of us (Y. M.) is on leave from Nagoya University, Japan.

Parachor and Critical Co-ordinates

In 1923, Macleod discovered an empirical formula¹ which was valid near the critical point of a pure substance

$$\sigma = \text{constant} \cdot (d_i - d_g)^4 \tag{1}$$

where d_l and d_g are the densities of the liquid and gas, respectively, and σ is the surface tension of the interface separating the liquid and gas. This formula was expressed by Sugden as2

$$P = \sigma^{1/4} M/(d_i - d_g) \tag{2}$$

where M is the molecular weight of the substance, and Pis a constant (characteristic of the substance) called the parachor. As is well known3, equation (1) is only approximately true; that is, the parachor varies slightly with temperature near the critical point. In recent years the

. COMPARISON OF EXPERIMENTAL AND THEORETICAL VALUES OF THE CRITICAL VOLUMES FOR A FEW REPRESENTATIVE SUBSTANCES

Substance	α	\boldsymbol{P}	p_c	T_c	v_c exp.	V_c formula
Equilibrium hydrogen	0·310	35·2	12·77	33	65·5	65·3
Methane	0·290	73·2	45·8	191·1	99	98
Methyl acetate	$0.255 \\ 0.231$	177·0	46·3	506·9	228	229
Water		52·4	218·3	647·4	56	55

parachor has fallen into desuetude, undoubtedly because it was linked2 to an empirical view of the structure of atoms and molecules, which is no longer acceptable. Nevertheless, equation (2), considered only as an approximate experimental law, can still be useful as will be seen

Recent numerical results4,5 show that the threedimensional Ising model, which is believed to describe correctly many real substances near the critical point, satisfies equation (1) within the precision of the numerical method. Thus, at least for such a statistical model, the existence of the parachor may have some theoretical justification*. An Ising model is defined by three parameters, for example, p_c , V_c , T_c , pressure, molecular volume and temperature at the critical point.

Dimension considerations show at once that for such a model

$$P = f(\alpha) \ p_c^{1/4} \ V_c^{13/12} \tag{3}$$

where $f(\alpha)$ is an unknown function of α , and α is the dimensionless parameter

$$\alpha \equiv p_c \ V_c/R \ T_c \tag{4}$$

where R is the universal gas constant. It happens that α varies only slightly from substance to substance. (If a were a constant the law of corresponding states would apply exactly.) Then an excellent representation for $f(\alpha)$ should be

$$f(\alpha) \simeq A\alpha^B \tag{5}$$

assuming that $f(\alpha)$ has no pathological behaviour. A and B are two universal but unknown constants. Comparison with experiments gives $A = 1.01 \times 10^{-2}$, B = 5/12 and

$$P = 1.01 \times 10^{-2} \alpha^{5/12} p_c^{1/4} V_c^{13/12}$$
 (6)

Equation (6) is a relation between the four parameters $(P, p_c, T_c \text{ and } V_c)$. V_c is the most difficult to obtain experimentally. Equation (6) is useful to obtain V_c , when P, p_c, T_c are known, or in practical units

$$V_c \text{ (cm}^3) = 7.10 \ P(\text{c.g.s.}) \ T_c \ {}^{4/18}_{\circ} \ p_c \ (\text{Atm})$$
 (7)

WE used equation (7) for all substances listed by Kobe and Lynn¹⁰ for which the critical co-ordinates are known. The parachor is always known either experimentally or using precise rules^{2,11}. The agreement between the experimental values and those given by equation (7) for V_c was better than 5 per cent. For most substances (75 per cent of cases) the agreement was even better than 3 per cent. This agreement is excellent considering the experimental uncertainty of V_c . There are about fifty substances for which P, p_c , T_c are known and V_c unknown. Equation (7) may be used with confidence to obtain a reliable value for V_c . Numerous empirical relations have already been proposed, linking the parachor and the critical co-ordinates^{2,7,10,11}. Most are a special case of equation (7) for a certain class of substances, for example, for a given α or a given p_c . Contrary to equation (7) none of them applies to all substances. In particular,none can be used at the same time for equilibrium hydrogen (largest α) and for water (one of the smallest α). In

 $\sigma \simeq \text{constant}$, $(d_1 - d_0)^3$

instead of equation (1).

^{*} Fowler's derivation of the parachor for a "classical" (van der Waals type) substance is incorrect. He assumed a discontinuous interface between bulk liquid and bulk gas, while it is well known. Interface between the interface becomes infinitely thick as the temperature approaches its critical value. Actually "classical" substances satisfy an equation of the form.

Table I we give a sample of four substances which cover the whole range of a. (Experimental results are from refs. 2 and 10.)

BIOPHYSICS

Electron Paramagnetic Resonance in Frozen and Dried Biological Materials

Kent and Mallard¹ and Truby and Goldzieher² have recently indicated that free radicals formed in organic material are artefacts, apparently resulting from lyophil-Our findings are not in agreement with this concept. We believe that lyophilization of living biological materials, of and by itself, produces few if any free radicals. Our investigations indicate that the electron paramagnetic resonance signals observed by others3-5 were the result of a reaction between oxygen and an unidentified component in dried specimens which formed free radicals during the interval between lyophilization and observation in the electron paramagnetic resonance spectrometer.

For several years we have been observing easily detectable free radical production in dried bacterial preparations^{6,7}. As long as oxygen was excluded, no free radicals were detected in dried bacteria, even at the highest sensitivity of our instrument. In the presence of dry air, however, we had to attenuate sensitivity to measure the signals formed.

In some experiments material was dried in a device which enabled the sample to be transferred into electron paramagnetic resonance tubes without exposure to air. Later, the samples were formed into pellets which could be dried in 4.4 mm internal diameter thin-wall 'Pyrex' sample tubes. This latter method of drying the samples is more convenient and more certain of excluding oxygen than is the method of packing in vacuum.

Fig. 1 presents results of an experiment in which rat liver was homogenized, frozen in small spheres and dried in the electron paramagnetic resonance cavity. The liver was removed from the rat, rapidly cooled by washing in cold saline, and homogenized with a 'Pyrex' tissue grinder. Large particles were removed by centrifugation to ensure the uniformity of the suspension. Drops of this homogenate were frozen in a mixture of 'Freen 112' and heptane to form spheres as described previously8. Pellets were transferred to the electron paramagnetic resonance tubes at -70° C and attached to a suitably trapped high vacuum system. Sublimation of water kept the pellets frozen after the tubes were inserted into the electron paramagnetic resonance cavity, so the strength of the electron paramagnetic resonance signal in the frozen material was easily determined before drying as well

as at intervals thereafter—all without interrupting the drying process. As shown in Fig. 1, the concentration of free radicals in either the frozen or dried sample was too low to be detected. Within five minutes after admitting dry air, an appreciable signal appeared at about g = 2.0045. It is evident that measurements made at any time after exposure to oxygen do not represent the concentration in the tissue before drying. Because Dettmer et al.³ stored their samples at room temperature for "lesthan 3 days" before examining them in the spectrometer, the conclusion they drew regarding the effect of time between killing the animal and the appearance of a free radical in the tissue at the time of freezing may not be They implied that free radicals observed in tenable. lyophilized tissue were present before the tissue was frozen. We recognize that there are limited amounts of free radicals in normal tissue. The bulk of the electron paramagnetic resonance signal Dettmer et al.3 observed. however, probably arose from subsequent reactions with oxygen because these workers apparently made no attempt to exclude air from the samples.

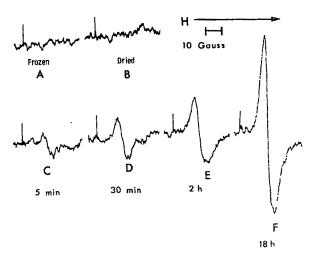

Fig. 1. Effect of drying (A and B) and exposure to air (C–F) on electron paramagnetic resonance spectra of rat liver homogenate. The short vertical line on each trace is b magnetic field marker. These spectra were obtained with a dual-cavity X-band Varian spectrometer, model 4500, with a 9 in. electromagnet and 100 kc/s field modulation. The modulation amplitude was approximately 3 gauss with a microwave power of about 30 mW.

With regard to the stability of the radical, Dettmer et al.3 stated that there was a severe loss of signal amplitude during 2.5 weeks and that moisture suppressed the electron paramagnetic resonance signal. In our studies we found that the stability of the radical was related to humidity and at any relative humidity above 30 per cent the signal intensity decreased after reaching a peak in less than 5 days. Fig. 2 shows the effect of humidity on both the increase and subsequent reduction in electron paramagnetic resonance signal intensity. We have observed that in dry air (<10 per cent relative humidity) free radical concentration remained unchanged for years.

Miyagawa et al.9 indicated that the paramagnetic resonance in dried biological substances was caused by sorbed oxygen because the signal decreased when oxygen was removed. We have found, however, that the signal intensity, developed in air, was not reduced by evacuation at 10-4 to 10-5 torr for 2-3 days. Morozova and Bluymen. fel'd4 also found that high vacuum did not reduce the signal in dried rat liver or spleen and they concluded that the reversibility mentioned by Miyagawa et al.9 was an artefact. In view of the relatively weak signals reported by Miyagawa et al. and the fact that the resonance curves seem to have a shape different from those in Fig. 1. we believe that the free radicals we find in dried tissue and bacteria are the result of a reaction between oxygen and some organic material in the sample-not just a result of

physical sorption of oxygen.

Dettmer et al.3 indicated that the largest signal was obtained from liver and the smallest from spleen. We and others4,8 found, however, that the spleen consistently produced a higher concentration of free radicals than the liver did. The most reasonable explanation of Dettmer's finding is that moisture in his sample may have caused rapid loss of free radicals because we have observed that dry spleen is more hygroscopic than dry liver.

It is difficult to identify or measure the material (free radical precursor) which reacts with oxygen to produce free radicals because this precursor is present in limited amounts and accumulation of the free radicals is influenced by many factors. A number of substances such as ethylenediamine tetraacetic acid (EDTA), sucrose, glucose, ribose or even sodium chloride inhibit or prevent subsequent free radical production when added to the tissues before they are frozen. In bacterial preparations the extent of free radical production seems to be a function of viability, and if cells were killed before lyophilization no free radicals were produced when samples were exposed to air6.

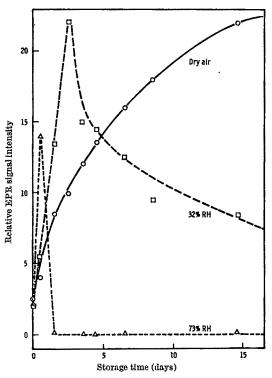

Fig. 2. Effect of relative humidity on electron paramagnetic resonance signal intensity of lyophilized rabbit liver. Saturated salt solutions were used to maintain relative humidity in air above the samples.

We have tried to determine the nature of the free radical Preliminary evidence indicates that two components are involved: one with a molecular weight between 50,000 and 100,000 and the other with a molecular weight less than 25,000. These react to form the precursor. Propyl gallate or adrenaline can react with the larger molecule to form a precursor which seems to be the same as that in whole tissue. The high molecular weight material seems to be heat stable. Although these studies on identification of the system in micro-organisms and tissues are incomplete, we believe that the act of lyophilization, per se, produces no free radicals in biological systems.

PHYSIOLOGY

Position of Onset of Fast Phase in Optokinetic Nystagmus

OPTOKINETIC nystagmus is the cycle of slow forward and fast return phases of the eye when it follows a continuous movement in the whole visual field. Although optokinetic nystagmus has been frequently studied in a variety of animals, there is no information as to how the point of onset of the fast return phase is determined. In the crab Carcinus both eyes respond to the movement of a striped drum, although one eye moves towards the midline while the other moves away from it. For both eyes to respond in either direction it is sufficient for one eye to see the drum1. J. Barnes, of this laboratory, has recently shown that the eye which makes the slow forward phase towards the midline "governs" the onset of the fast phase and leads by 30-50 msec (unpublished results).

The onset of the fast phase is not directly controlled by proprioceptors or mechanoreceptors of the eye socket. Impulses to muscles which bring about the fast phase can be recorded in the oculomotor nerve of a blind eye which is driven by the other eye, and their pattern is unchanged by clamping the responding eye or even by The same result is obtained when the removing it1. oculomotor nerve of the driving eye is cut so that there is no movement or muscle tension in the driving eye, and no visual information from the blind moving eye2. Furthermore, the position reached by either eye or the tension in muscles does not control onset of the fast phase because a blinded eye, driven by a clamped seeing eye, can itself be clamped or set in different positions with no effect on the frequency of nystagmus, as recorded in the nerves.

The onset of the fast phase is not controlled directly by the visual input, as optokinetic memory experiments showed3. A small movement of a striped drum around the crab is made during a dark period; when the light is restored the eyes follow the drum. Because the eyes respond while the drum remains stationary, the stripes will seem to move in the opposite direction to the response. When a clamped, seeing eye drives a blind, moving eye in this experiment, both the seeing eye and the drum remain stationary when the light comes on. The blind eye can be induced to undergo a nystagmus at any time during its response by first moving it under the control of the illuminated drum. Experiments such as these show that the onset of the fast phase cannot be controlled directly by what the crab sees at that moment. There is no distinction between the mechanism of onset of the fast phase and that which determines the impulse frequency to the muscles which move the eye. The stimulus for each is the total movement seen since the previous fast phase. Each fast phase wipes clean the mechanism for a fresh start on the efferent but not on the afferent side.

The question thus arises as to how the brain of the crab acquires the information to make the fast return phase at the appropriate position of the eye without visual or mechanoreceptor clues. In any one crab the position of the onset of the fast phase is constant to about 1°, but crabs differ greatly in this respect. We have shown that at the onset of the fast phase the slow motor impulse frequencies to the appropriate eye muscles which cause the slow forward phase vary considerably between crabs, but each crab has eye movements which are suited to the anatomy of its own exoskeleton. To test whether learning is involved, we tried the following experiment. With both eyes free to move and the left eye blinded, movement of the right eye was recorded with the slow phase towards the midline, that is, an eye leading in the fast phase. When the right eye reached a point about 1° before the normal onset of the fast phase, the crab received a shock to the carapace in the area innervated by the antennular or tegumentary nerve. If this did not cause a withdrawal reflex, further shocks were received at about 10/sec until the eye was withdrawn inside the limit beyond which shocks were given. Meanwhile, the movement of the drum continued to drive the eye towards the point of shock. At first the shocks cause retraction before the eye makes a normal fast phase, but as long as only a small change is demanded of the system, the onset of the fast phase soon appears after a shorter traverse so that the shock is avoided. The adaptive change lasts for many minutes before the excursions in nystagmus recover their former size. We have found that records of the instantaneous frequency of muscle twenty-one, which is responsible for the slow forward phase towards the midline, show the same phenomenon. These results are now in preparation. The onset of the fast phase occurs at a lower motor output frequency to muscle twenty-one after treatment with shocks which would cause eye with-This shows that the effect is not caused by a sustained partial withdrawal which would merely hold the eye away from the midline. A full description of the interaction between the eye withdrawal reflex and the optokinetic response, in terms of motor impulse frequencies, is in preparation. This adaptive change, however, can scarcely be classed as conditioning because shocks delivered without reference to eye position also cause the fast phase to occur after a shorter than normal traverse of the eye, or after a less than normal frequency of slow motor impulses to muscle twenty-one. Shocks which cause withdrawal of the eye have no lasting effect on the eye position or on the frequency to the relevant muscle, but subsequent fast phases occur at a lower frequency and therefore further from the midline.

The significance of these results is perhaps as follows. The brain seems to make no use of information on the position of the eye except that which is equivalent to the motor output to the eye muscles. When the slow phase is towards the midline, contact of the eye with the edge of the socket will excite mechanoreceptors of either the eye or the socket which can in fact induce eye withdrawal. Whether or not there is a complete withdrawal, repeated excitation in these nerves shortens the traverse of subsequent nystagmus movements by influence on the onset of subsequent fast phases. The withdrawal reflex is a movement away from the midline, and the fact that the eye, making a slow phase towards the midline, governs the onset of the fast phase for both eyes agrees with the idea that the withdrawal reflex provides the reinforcament. By this means the animal could learn the fine control of the position at which it must make a fast phase to avoid running its eye into the edge of the socket, which changes at each ecdysis. Such a mechanism, compatible with the observed independence of proprioceptive

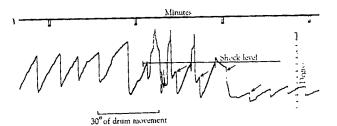

Fig. 1. Effect of shocks to the socket region (in this case to the right antennule) on the initiation of the fast phase by the right eye, with the striped drum moving towards the midline for this eye. Horizontal line marks the point beyond which further movement in the slow phase caused shocks to be applied at about 10 c/s. Note the fast phase occurring at successively lower points (arrows) after each period of shocks and the new level of much earlier fast phases which no longer reach the position where shocks are delivered.

control, would provide the animal with a means of assessing the detail in its own anatomy and would explain the differences between individuals. I do not believe that the whole efferent pattern is learned, but only the modification of some aspects of the fine detail. Accuracy of following in the slow forward phase is achieved by the feedback loop which is the consequence of the movement of the eye. Although the tests with indiscriminate shocks on the onset of the fast phase show that the shortening of the eye traverse is not caused by the association of the shock with the point at which it is received, they are irrelevant to the situation in the crab because the direction of the effect is that required to be adaptive.

Comparable experiments have shown that the postural control of the legs in insects4 is also achieved without proprioceptive feedback by a mechanism which seems to use the appropriate efferent motor frequency as its only means of knowing the position of the leg⁵. In the insect system, however, there proved to be an element of conditioning and the efferent frequency can be modified so that it is either greater or less than the initial spontaneous rate. The crab eye preparation is the second which illustrates an adaptive mechanism in which a non-specific reinforcement (stimulation of a mixed sensory nerve of the relevant anatomical area) influences a subsequent part of a central programme which is not directly under proprioceptive control. It is intriguing to suppose that this type of mechanism of plasticity is the one most suited to animals in which many of the activities are controlled by central programmes of motor impulse sequences which are not instantaneously monitored by mechanoreceptors.

Reduction of Strontium Absorption in Man by the Addition of Alginate to the Diet

CONSIDERABLE effort has been expended in the search for a non-toxic substance which will reduce the intestinal absorption of radioactive strontium without interfering with calcium absorption. A compound which approaches these requirements is an extract from brown seaweed known commercially as sodium alginate. It consists of a mixed polymer of L-guluronic and D-mannuronic acids. of which the ratio, referred to as the G/M ratio, depends on the botanical source and the method of extraction.

The effectiveness of sodium alginate in reducing strontium absorption in both man and laboratory animals has often been investigated¹⁻¹⁰, but, because of the variability in the composition of the alginates used, comparison of results has been difficult. When, however, various commercial forms of sodium alginate (from Alginate Industries Ltd., 22 Henrietta Street, London, WC2) with measured G/M ratios were added to the normal diet of the rat, the alginate, 'Manucol SS/LD', with the highest G/M ratio was the most effective in reducing the skeletal uptake of strontium without affecting the calcium uptake.

An alginate derivative, referred to as O.G.1, and with a G/M ratio of 97 per cent, has now been prepared in this laboratory¹¹. When O.G.1 was compared in rats with 'Manucol SS/LD' with a G/M ratio of 71 per cent, a correlation was again observed between the guluronic acid content of the salt and the degree of reduction of strontium absorption. Calcium uptake was not affected.

In view of these results an experiment was designed to test the relative efficacy of 'Manucol SS/LD' and O.G.1 in suppressing strontium absorption in man, and the results of the experiment are presented in this communication.

The two alginates tested, 'Manucol SS/LD' with a G/M ratio of 71 per cent and O.G.1 with a G/M ratio of 97 per cent, were dissolved separately in homogenized milk in the ratio 10 g to 1 l. of milk. The strontium-87m, as a neutral solution of the chloride, was added to the mixtures of milk and alginate immediately before ingestion. In the control experiments, the milk contained only the radioactive marker.

All volunteers adopted the following regimen. Subjects fasted overnight and at about 09.15 h each drank 250 ml. of milk containing 10 μc . of strontium-87m (control), or milk containing the same radioactive marker and either 'Manucol SS/LD' or O.G.1. The same quantity of milk, or milk with alginate but unlabelled, was ingested at 12.30 h. No other liquids or solids were taken during the period of experiment (09.15–16.15 h). Three subjects repeated the tests in control and the two experimental conditions with an interval of 1 or 2 days between each test to allow for the decay of the strontium-87m and excretion of the alginate additives.

Two hours after the radioactive dose had been given, 25 ml. of blood was taken by venipuncture into a heparinized centrifuge tube and the plasma separated for counting. Urine was collected for 7 h from the time of ingestion of the radioactive dose and the count rate in 10 ml. samples of plasma or urine was compared with that of a standard source of strontium-87m in a well type scintillation counter. The percentage of the dose in 1 l. of plasma and in the 7 h urine was derived from these observations. The calcium contents of the milk and urine were measured by flame spectrophotometry.

In Table 1 the concentrations of radioactive strontium in plasma, expressed as the percentage of the dose/l., are shown for all four subjects in each experimental situation. Individual results usually differ from their means by less than 5 per cent and the lowest plasma concentration of strontium-87m occurred in all subjects after the ingestion of O.G.1.

Table 1. CONTENT OF STRONTIUM-87m IN THE PLASMA OF FOUR SUBJECTS, 2 H AFTER AN ORAL DOSE

Amounts of strontium-87m excreted in the urine during the 7 h following the dose are given in Table 2. Individual results and means are shown for each subject as in Table 1, but, unlike the results for plasma, the individual values differ from their means by 10-20 per cent. Concentrations of strontium-87m in the urine follow the same pattern as the plasma, with the lowest output occurring after ingestion of O.G.1. The high calciuria and strontiuria for subject J. L. has been observed before 12.

The ratios, experimental to control, of strontium-87m in plasma and urine are given in Table 3. Results for O.G.1 show that the marker concentration in the 2 h plasma samples was reduced about six-fold and in the 7 h urine samples about eight-fold, compared with the controls. Treatment with SS/LD produced a three-fold decrease of strontium-87m in the plasma and a four-fold decrease in the urine compared with the controls.

Table 4. MEAN CONTENT OF CALCIUM IN URINE FROM EACH OF THE FOUR SUBJECTS IN THE THREE EXPERIMENTAL SITUATIONS

	Calciu	n (mg/7 h)	
Subjects	Milk	Condition Milk + SS/LD	Milk + O.G.1
E. H.	47.5	31.5	30.9
G. H.	68.5	61.9	58-9
A. S.	44.2	28.9	32.1
J. L.	151	162	117

Concentrations of calcium in the urine of the four subjects are given in Table 4. In general, there is a reduction in urinary calcium after milk supplemented with either SS/LD or O.G.1 had been ingested.

Some of the advantages of using strontium-87m to estimate intestinal absorption have been discussed previously¹³. The short half life (2·8 h) was particularly useful in these studies because the whole series of tests could be performed in 3 weeks.

Milk was considered to be a satisfactory form of diet, because it has been shown that strontium in milk is fully available for absorption¹⁴ and it was desirable to start with a basic material which was free from substances which might inhibit uptake of strontium. Errors resulting from non-uniform mixing of the alginates with the diet were avoided, for the two alginates were dissolved in the milk. Variation in composition between different batches of milk was small and the constancy of the calcium content, 1·0–1·1 g/l., was an advantage as it was an approximate equivalent to the 10 g of alginate added to each litre of milk. This 10:1 ratio of alginate to calcium was also used in the rat diet^{5,8}.

Concentrations of radioactive strontium in plasma (0.48-0.72 per cent dose/l.) observed during the control experiments were in agreement with values found earlier^{13,15,16}. Following the ingestion of 'Manucol SS/LD' there was a mean reduction of 64 and 75 per cent in the concentration of radioactive strontium in the plasma and urine, respectively. These values compare well with the reduction of 66 and 71 per cent in the radioactive marker

content of plasma and urine of rats after feeding with SS/LD⁵. Absorption in these rats, estimated from the sum of the radioactive strontium skeleton and urine, was reduced by 73 per cent.

Concentrations of strontium-87m in plasma and urine were even lower after O.G.1 had been ingested. The urine indicated a reduction in absorption of 87 per cent and the plasma indicated a reduction of 83 per cent. These results again correspond well with a reduction of 78 per cent found in the urine of rats fed on a diet containing $O.G.1^{s}$. Hesp⁴ also found that urine showed a greater reduction than did the plasma, but both values were in reasonably good agreement with the figures for true absorption as measured by means of a whole body counter.

Results for the calcium content of the urine are incon-There is a slight indication in three subjects that the calcium content in the urine falls after the ingestion of 'Manucol SS/LD' or O.G.1, but further experiments would be necessary to verify this point. When rats were fed for 1 yr on a diet containing a 10 per cent supplement of 'Manucol SS/LD', however, absorption and excretion of calcium were found to be normal (unpublished work of T. E. F. Carr).

I thank T. E. F. Carr and Dr G. E. Harrison for their help, Dr D. W. H. Barnes for taking the blood samples and Hilda Shepherd for technical assistance.

Coupling Resistance of Double **Barrelled Microelectrodes**

THE double barrelled microelectrode is a convenient way of introducing two electrode tips into the same cell for simultaneously passing a current and recording. The chief source of artefact is the coupling resistance (Rc) (ref. 2), which is manifest when a current passed through the stimulating barrel causes a voltage to appear at the recording barrel. It presumably represents the resistance of electrolyte immediately adjacent to and shared by both tips, for most of it disappears if the very tip of the electrode is broken off. When current is passed from an intracellular double barrelled electrode, the coupling resistance with the electrode intracellular (Re_i) is in series with the cell membrane resistance viewed by the recording barrel. Rc_i must therefore be subtracted from the observed input resistance to obtain the true value of the input resistance and of voltage displacements. The problem is to know the value of Rc_i , because Rc can only be measured directly with the electrode extracellular. The simplest method² is to assume that Rc does not change on impalement, which is to assume that Rc_i is the same as Rc_{e^-} the value obtained on withdrawal from the same cell.

These experiments were designed to test this assumption. The voltage record from the recording barrel of a double barrelled electrode was monitored by a second, nearby intracellular electrode to give an independent measure of the input resistance, Rm. Rc_i was then determined by subtracting Rm from the value for $(Rm + Rc_i)$ found with the double barrelled electrode. The cells were fibres of the sartorius muscles of the frog Rana temporaria (or, in the case of electrodes 9 and 10, the toad Bufo bufo). They were bathed, at room temperature, in frog Ringer solution, to which 1 mg/ml. cocaine had been added to prevent electrical and mechanical responses. Double barrelled micropipettes were made and filled with 3 molar potassium chloride as described by Wardell³. The resistance of each barrel in the bathing solution was accepted in the range 17-90 M Ω , and the coupling resistances (Rc_e) ranged from 40–650 k Ω . No further selecting was done, hence the series represents the first ten electrodes to satisfy these criteria. Conventional methods of stimulating and recording were used with a beam-splitting device to display the three records (current and voltage from separate barrels of the double electrode, and voltage from the separate recording electrode) on a Tektronix type 502 oscilloscope, where they were photographed. Single fibres were impaled simultaneously with both the double and the single barrelled electrodes, the two being less than 50µ apart along the fibre. Five current pulses of 200 msec duration, ranging in strength from 1 to 10×10^{-8} amp, were passed in each direction through the lower-resistance barrel of the double barrelled electrode. The latter was then withdrawn and the current pulses repeated to obtain Rce. For each current pulse the voltage recorded by the single electrode was subtracted from that recorded by the double electrode. This difference was plotted against the strength of the applied current, and Rci was taken as the slope of a straight line fitted to these points by eye. A fluctuating voltage record (representing instability of Rc_i) was sometimes obtained from the double barrelled electrodes, particularly with the highest current pulses. Such records were discarded. No correction was considered necessary for the separation of the electrodes along the fibre, because the distance of 50µ is much smaller than the space constant of 2 mm found by Fatt and Katz4. Any error caused by this assumption would tend to overestimate Rci. On an average, three randomly selected fibres were studied with each of the ten double barrelled electrodes.

The results are summarized in Table 1 and Fig. 1. The chief finding was that the coupling resistance increased in twenty-six out of the thirty impalements. Over the series the mean value of Rc_e was 322 k Ω , while Rc_i was larger by a mean value of 316 k Ω . In threequarters of the impalements the increase was less than 100 per cent of Rc_e , ranging in value from $-100 \text{ k}\Omega$ to $+360~k\Omega.$ The remaining quarter included four very large increases, the worst being 1,380 $k\Omega$ (= +430per cent of Rce). In addition, marked rectification sometimes appeared, as shown in Table 1.

The large increases only occurred with electrodes of higher Rce. Of the eight impalements with Rce less than 250 k Ω (mean = 156 k Ω), all increases were smaller than 200 k Ω (mean=112 k Ω =95 per cent of Rc_e). Of the twenty-two impalements with Rc_e greater than 250 k Ω (mean = 383 k Ω) the mean increase was 392 k Ω (= 112 per cent of Rce) and it was this group which contained all the large increases. As seen from Fig. 1, one cannot predict that any given electrode of high Rce would necessarily give more error than one of lower Rce, but, in general, electrodes of Rc_e less than 250 k Ω have a smaller and

more consistent increase on impalement than those of larger Rc_e . There was no correlation between barrel resistance and the increase of Rc on impalement.

Thus, over the whole series, Rc nearly doubled on It is not surprising that the increase impalement. occurred, for two reasons. First, there is evidence that the specific resistance of myoplasm is three times that of the external solution⁵. This would cause part of Rc to rise by 200 per cent, but would probably not affect any component of Rc arising within the tip of the pipette as a result of, for example, the interbarrel septum finishing short of the tip. The resultant increase in Rc would thus be expected to be less than 200 per cent. Second, the area in and around the very tip of the pipette, which would be expected to contribute most of Rc, is also the part most liable to be blocked by cell organelles or membranes which could cause Rc to rise manyfold. It is tempting to speculate that such a blockage occurred in those four impalements (Fig. 1) in which Rc increased by exceptionally large amounts. If this is true, it is surprising that it did not happen more often, because the cell is full of membranes and organelles which could cause blockage. Over the whole series, allowance for a

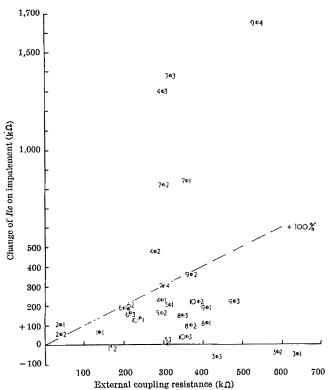

Fig. 1. Relationship of the change of coupling resistance on impalement to the external coupling resistance. Each point is denoted by the number of the electrode (1 to 10) followed by the number of the fibre impaled by it (1 to 4).

doubling in Rc on impalement would have given a good correction of the error, but where Rc_c was greater than 250 k Ω , individual records could not be relied on because of the occasional very large increases. For individual records to be meaningful, Rc_c should be as small as possible and in any case smaller than 250 k Ω , while the cell input resistance should be relatively large compared with Rc_c . Even then there is no guarantee that an individual electrode is giving an accurate record; results using several electrodes should thus be compared.

The exact numerical values obtained here should not be assumed to apply directly to other series of electrodes because of likely differences in their physical properties, but the trend might be expected to be followed.

Relation between Ganglion Cell Activity and the Local Electroretinogram of Cat Retina

DELAY in the decay of the late receptor potential (late RP) of monkey retina has been demonstrated accompanying a progressive increase in the intensity of a 20 This delayed decay of the late receptor potential is accompanied, in the same retina, by a delayed decay of the d.c. component of the local electroretinogram². The d.c. component is thought to originate in the inner nuclear layer, and the late receptor potential in the receptor layer^{1,3}, and so the authors suggest that "the late receptor potential of the receptors is a crucial event which controls the activity of cells of the inner nuclear They indicate further than other off-responses of the visual system might be similarly related to the late receptor potential if they could be delayed by increases of stimulus intensity. With this in mind, I observed a relevant effect of stimulus intensity on the discharge pattern of cat ganglion cells. The on-response, at high intensities, continued into the off-period instead of terminating at the "off" of the flash. In addition, this ganglion cell effect seemed to be related to the behaviour of the d.c. component of the local electroretinogram.

Ganglion cell discharges and intraretinal slow potentials were recorded in unanaesthetized cats, decerebrated and paralysed with gallamine triethiodide. A closed eye recording and stimulating technique, almost identical with that described earlier⁴, was used. All potentials

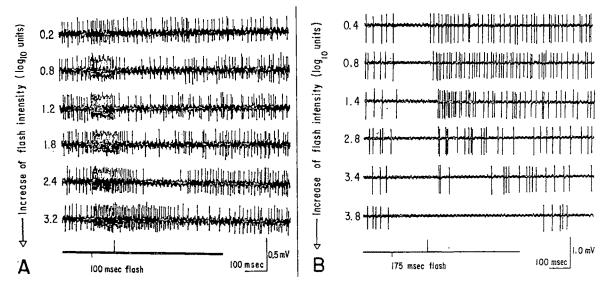

Fig. 1. The ganglion cell on-response as a function of flash intensity. A, On-excitation of a ganglion cell as a function of flash intensity. A 0.33 mm stimulus spot, 100 msec in duration, was centred on the microelectrode in the area centralis, and repeated once every five seconds. A 2.0 mm adapting spot was also centred on the electrode. The stimulus spot was optimal in size for stimulation of the receptive field centre of this ganglion cell as determined by an area-threshold technique. The intensity of the adapting spot was 10²⁻⁶ trolands while the threshold intensity of the stimulating spot was 10²⁻⁶ trolands. Threshold intensity was defined as the intensity that produced a stimulus-locked change in spontaneous activity that was both audible and visible to the experimenter with every flash. Amplification was condenser-coupled with the bandpass set from 30 c/s to 30 kc/s. Negative responses are displayed upward. B, On-inhibition of a ganglion cell as a function of flash intensity. The intensity of the adapting spot was 10¹⁻⁶ trolands, and the threshold intensity of the stimulating spot was also 10¹⁻⁶ trolands. Otherwise, the conditions of stimulation and recording are the same as in A.

were recorded with 3 molar potassium chloride glass micropipettes referred to a vitreal chlorided silver wire. The cornea was protected by a contact lens and the pupil was dilated by instillation of 10 per cent phenylephrine hydrochloride.

A dual-beam ophthalmoscope⁵ was used for stimulating and viewing the retina with tungsten filament lamps in both beams. A shutter in the stimulus beam produced step functions adjustable in duration and rate with equal rise and fall time of 1 ± 0.05 msec. The stimuli were in the form of spots (diameter on the retina: 0.06 mm-2.0 mm), and annuli focused on the retina after the refractive error of the eye had been corrected. The maximum available retinal illuminance in the stimulus beam was 105,9 trolands. The receptive field centre was first located by centring the flash on the tip of the microelectrode, and a spot was chosen with a diameter which stimulated optimally only the centre mechanism (area-threshold technique)6,7. A background spot, larger in diameter than the receptive field, was also centred on the micro-

Fig. 1 shows the responses of ganglion cells to flashes of increasing intensity. At moderate intensities (0.5-1.5 log₁₀ units above threshold), the on-response abruptly terminated at the "off" of the flash and was followed by an off-response of opposite sign, for example, in Fig. 1Bon-inhibition was followed by off-excitation 8-14. Actually, the on-response always continued past the off-transient of the flash for a brief period of time (usually 10-25With additional increases in flash intensity, however, a threshold was reached at which the onresponse extended farther into the off period. Additional increases in intensity enhanced this extension of the onresponse by increasing its strength and duration. was observed in both on-excited and on-inhibited receptive field centres, as an extension of excitation, in the former (Fig. 1A, 1.8-3.2), and of inhibition (Fig. 1B, 2.8-3.8), in the latter. This phenomenon occurred only when the flash intensity was well above threshold and was most clearly defined at intensities greater than 2.0 log10 units above threshold. Lowering the intensity of the background beam lowered both the threshold of the onresponse and the threshold for extension of the onresponse. Extension was observed at all the flash durations tested between 5 msec and 1 sec. It was still observed with flashes smaller than the receptive field centre; with very small flashes (area $< 0.01 \text{ mm}^2$), the threshold was raised.

This effect occurred at high intensities relative to threshold ($>2.0\log_{10}$ units), and so stray light may also have been a significant additional stimulus. It could be postulated that stray light stimulated the receptive field surround and that extension was actually an off-response of the surround appended to the on-response from the centre. At the intensities necessary to produce extension, however, the response of the unit was almost always dominated by the centre mechanism. Even, with stimulation of the surround alone, using annular flashes, stray light often triggered the centre mechanism making it difficult to study the surround on-response at high flash intensities.

The off-response was also altered at high flash intensities. In some cells the off-response, although weakened, could still be identified after the termination of the extended on-response (for example, the inhibitory period after the on-excitation in Fig. 1A), while in others it could not be identified easily⁸⁻¹⁰. The persistence of the off-response at high intensities was also related to the duration of the flash. For example, with flashes of 250 msec and longer, in on-excited cells, a brief period of inhibition sometimes remained at a short latency from the "off".

The appearance of the local electroretinogram in the light-adapted area centralis is shown in Fig. 2. potential was presumably recorded just distal to the outer margin of the inner nuclear layer, because the microelectrode had been adjusted to record a maximum offresponse¹⁵. It consisted principally of a negative b-wave and a negative d.c. component, together forming PII of Granit¹⁶. Following the off-transient of the flash, the d.c. component formed an off-response by decaying rapidly toward the baseline. At moderate intensities (<1.5 log₁₀ units above threshold), the off-response always followed the off-transient of the flash at a short latency, for the d.c. component continued into the off-period for only 15-25 msec. Intensities which were much greater than threshold (>2.0 \log_{10} units) always altered this response. The principal effect of high intensity illumination was to increase the duration of the d.c. component. In Fig. 2,

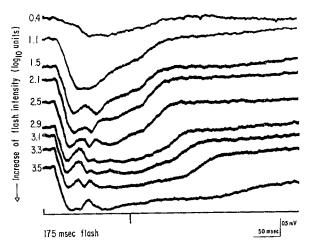

Fig. 2. The local electroretinogram as a function of flash intensity. A 1-0 stimulus spot, 175 msec in duration, was centred on the microelectrode in the area centralis and repeated once every five seconds. A 2-0 mm adapting spot was also centred on the electrode. The stimulus spot was optimal in size for the production of a local electroretinogram at the lowest stimulus intensity as determined by an area-threshold technique. The intensity of the adapting spot was 10¹⁻² trolands while the threshold intensity for the stimulus spot was 10¹⁻⁴ trolands. Threshold intensity was defined as the intensity that produced a local electroretinogram, 0-1 mV in amplitude, with every flash. Intensities are specified in log₁₀ units above threshold. Amplification was direct-coupled. Positive responses are displayed upward.

3.3, a continuation of the d.c. component into the offperiod and a delayed off-response are both observed. At maximum intensity, the d.c. component continued into the off-period for several hundred msec, the slope of decay was markedly reduced (Fig. 2, 3·5) and the off-response became difficult to identify¹. The effects on the decay of the d.c. component were present at all flash durations tested between 5 msec and 1 sec, but were most prominent at flash durations less than 500 msec.

The local electroretinogram was usually recorded by centring a 1.0 mm diameter spot of light on the microelectrode. Larger spots did not alter the threshold for this response 18. With spot diameters of less than 0.33 mm, the threshold of the local electroretinogram was increased along with the threshold for modifying the offresponse. With very small spots (0.01 mm²), a decrease in the slope of decay could still be observed.

The bipolar cells probably give rise to the d.c. component1 and also are the principal source of ganglion cell input19, so that these results imply that the d.c. component of the local electroretinogram contributes to the formation of ganglion cell responses.

Ventral Root Afferent Fibres and the Recurrent Inhibitory Pathway

RENSHAW1 showed that stimulation of ventral roots of the cat spinal cord may inhibit motoneurones. This also occurs when muscle nerves are stimulated in preparations with cut dorsal roots. Renshaw proposed several alternative hypotheses to account for this. One was that antidromic action potentials in motor axons propagate along collaterals which terminate within the ventral horn2 and inhibit motoneurones either directly or through an inter-The discovery by Renshaw of ventral horn interneurones which were discharged repetitively by ventral root stimulation gave support to this idea. Eccles, Fatt and Koketsu³ reported evidence for synaptic links between cholinergic terminals of ventral root axons and the interneurones of Renshaw and between the interneurones and motoneurones. They also provided evidence against a second hypothesis of Renshaw that recurrent inhibition may be produced by interaction between the dendrites of motoneurones. There is as yet little direct evidence against the third hypothesis of Renshaw that afferent fibres within the ventral roots might inhibit motoneurones. Such afferents would have to arise, at least in part, from muscle to account for recurrent inhibition produced by muscle nerve stimulation. There is evidence for the presence of afferents in ventral roots. Sherrington4 found as many as forty degenerating axons in chronically sectioned ventral roots. He confirmed previous observations that there are often a few ganglion cells within the ventral root, although he failed to demonstrate a relationship between the "recurrent" afferent fibres and the ganglion cells. Ventral root afferents have recently been described in the cat⁵ and the rat⁶; at least some of them appear to arise from muscle6.

Because of the great theoretical interest in the recurrent inhibitory pathway, it seemed advisable to investigate the role of ventral root afferents in this pathway. One or more ventral roots were sectioned intradurally under pentobarbital anaesthesia in each of five cats. Aseptic procedures were used and broad spectrum antibiotics were given following the surgery. The animals were kept for 7-18 days. The dissection during the terminal acute experiment involved re-exposure of the spinal cord and preparation of roots, including the chronically sectioned ones, for stimulation or recording. Glass microelectrodes with initial resistances of about 10 M Ω were employed for recording from single units within the spinal cord. They were filled with I molar potassium acetate saturated with methyl blue. Details of equipment and procedures can be found in a recent paper from this laboratory?. The dye was used for marking the positions of neuroness. Records were made from Renshaw cells and from moto-The appropriate spinal cord segments and neurones. roots were preserved in neutral formalin for histological controls. Serial sections of the central ends of the chronically cut ventral roots were stained and examined for the presence of ganglion cells. Although three of the ventral roots contained an occasional ganglion cell (1, 2 and 4, respectively), there were none in three other roots (including the ones employed for Fig. 1A, B and D). It was possible to demonstrate the presence of a recurrent inhibitory mechanism in all the animals, and the range over which the recurrent inhibition could be graded exceeded the largest number of ganglion cells observed. Inhibitory postsynaptic potentials were recorded from fifteen of seventeen motoneurones. The motoneurones were identified by antidromic invasion of an action potential when a chronically sectioned ventral root was stimulated10. Recurrent inhibitory potentials were observed when the stimulus strength was at or below threshold for the motor axon3. In three experiments, records were made from a total of five Renshaw cells, all activated by stimulation of the central stumps of chronically sectioned ventral roots. It was, in addition, possible to demonstrate recurrent inhibition of the monosynaptic reflex.

Fig. 1 illustrates the results of these experiments. A and B are intracellular records from a motoneurone. Stimulation of a chronically sectioned ventral root evoked the antidromic action potential in A. When the stimulus strength was lowered below threshold for the motor axon of this cell, a recurrent inhibitory postsynaptic potential was observed (B). The extracellular field potential shown in C was a response to stimulation of a chronically sectioned ventral root in another experiment. Similar field

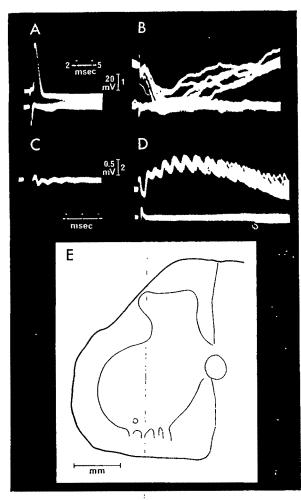

Fig. 1. The electrical records in A-D were made from the lumbosacral spinal cord in cats with chronically sectioned ventral roots. The upper traces in A and B were recorded intracellularly from a motoneurone, identified by antidromically conducted action potential (A) which resulted from stimulation of the chronically sectioned LT ventral root. When the stimulus strength was below threshold for the motor axon, a recurrent inhibitory postsynaptic potential was observed (B). The lower traces were recorded from the dorsal root entry zone by a ball-tipped platinum electrode. The trace in C is the field potential recorded extracellularly from a population of Renshaw cells by a microelectrode placed in the ventral horn. The stimulus was applied to the chronically sectioned SI ventral root. The action potentials shown in D were recorded intracellularly from a Renshaw cell damaged by the microelectrode impalement. The position of this neurone was marked and found to be at the site shown in the drawing in E. The upper time scale is 2 msec for A and 5 msec for B. The lower time scale is for C and D. The upper potential scale is 20 mV for A and 1 mV for B. The other is 0.5 mV for C and 2 mV for D.

potentials have been associated with the discharge of a population of Renshaw cells³. The burst discharge in Dwas recorded from a Renshaw cell following stimulation of a chronically sectioned ventral root. The microelectrode probably damaged the neurone, because the recording was intracellular and yet the action potentials were very small. The position of this Renshaw cell was marked by the electrophoretic ejection of methyl blue from the electrode. The cell was in the ventral part of Rexed's lamina VII¹¹, just medial to the motor nucleus (Fig. 1E). This position is characteristic of Renshaw cells^{7,8}.

There is at least one report consistent with these findings. Eccles, Libet and Young12 in their study of chromatolytic motoneurones observed recurrent inhibitory postsynaptic potentials in response to stimulation of chronically sectioned ventral roots. They made no histological sections, nor did they report finding Renshaw cells activated by stimulation of the same ventral roots.

It can be concluded that, although there are afferent fibres in ventral roots, these are not essential for the production of recurrent inhibition.

Calcification of Cell Nuclei in Experimental Necrosis in vivo

WE have reported previously1-3 that calcium, phosphorus. magnesium, lipids and polysaccharides can be deposited in the nuclei of dead cells in vitro. In such a nucleus a highly refractile granule is formed which grows in size. and, in suitable conditions, structures many times the size of a cell may grow out from the granule3. This may be pertinent to the study of certain processes in the organism, such as the calcification of necroses. arteriosclerosis and other cases of pathological calcification3 and so it seemed important to ascertain whether the phenomenon also occurs in the nuclei of dead cells in vivo. We therefore examined kidney tissue with ischaemic necroses caused by ligature of blood vessels4,5. Such necroses were known to calcify rapidly4-7 but the nature of the calcification was unknown.

In four male Wistar rats each weighing 230 g the left kidney was ligatured to cut off completely its blood supply. In two of the rats the kidney was removed for examination after 6 days and in the other two after 30 days. calcium content was assessed in each case as follows. The kidney was weighed after extirpation and dried overnight at 105° C. The dry matter was triturated and extracted with 2 ml. of 0.1 normal nitric acid for 5 days.

Calcium was assessed chelatometrically in the tissue extract and was calculated in g/100 g wet weight. Samples for histological examination were fixed in 10 per cent formalin and embedded in paraffin wax. Sections were stained with haematoxylin and eosin. Calcium was detected by the Kóssa reaction.

The normal kidney of a 230 g rat weighed 0.8 g; it was 1.4 cm long, brownish-red in colour and contained about 0.09 per cent calcium. Six days after ligature the kidney was a normal size but it was greyish white and the calcium content had risen 0.2 per cent. Thirty days after ligature the kidney was much smaller than that of a control animal. It was furrowed, yellowish grey in colour and contained 3.7 per cent calcium—a forty-fold rise in calcium content. Sections from kidneys 6 days after ligature showed nuclei with and without deposited calcium (Figs. 1 and 2). Calcification of the nuclei varied in intensity. In some nuclei there were only a few granules giving a positive reaction for calcium, while in others this reaction was so strongly positive that only phase contrast microscopy could show that the calcified masses were cellular nuclei (Fig. 2). In sections made 30 days after ligature, haematoxylin and eosin staining revealed many basophilic granules varying in size in a wide area beneath the surface of the kidney. Some basophilic granules were suggestive of nuclei in size and shape, and in all of them the reaction

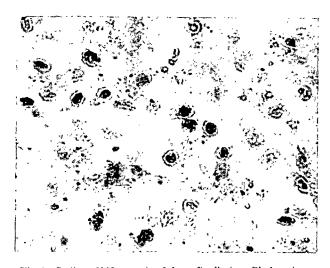

Fig. 1. Section of kidney cortex 6 days after ligature. Black spots are nuclei showing a calcium-positive reaction. Nuclei without calcium are also present. (×200.)

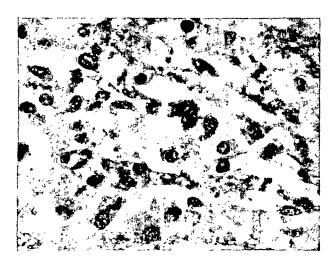

Fig. 2. Phase contrast microscopy of the same site as in Fig. 1 showing that calcium is deposited in the nuclei. (×200.)

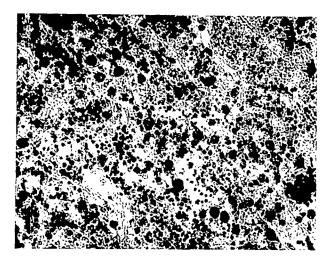

Fig. 3. Section of kidney cortex 30 days after ligature. Basophilic calcium-positive granules. Some structures resemble nuclei. (×100,)

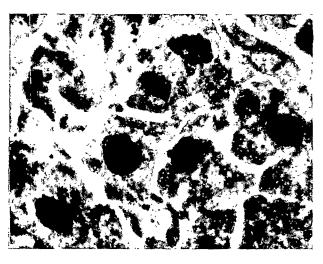

Fig. 4. Phase contrast illumination of same site as in Fig. 3. According to the position of the calcium-positive fragments it is evident that they were nuclei originally. (\times 450.)

for calcium was positive (Fig. 3). In preparations stained by the method of Kóssa, phase contrast microscopy in some cases revealed that the structures suggestive of nuclei occupied the centre of partially disintegrated cells and that really they were nuclei in which large amounts of calcium had been deposited (Fig. 4).

Our findings show that the nuclei of dead cells can calcify in vivo. It is, however, to be expected that processes occurring in vivo differ somewhat from those in vitro. We presume that there is a "nucleating material" in the nuclei of cells and that this material asserts itself only after the death of the cell. Here the term nucleating material is understood in the broadest possible sense. Our pilot experiments showed that DNA is one such substance. This nucleating material is the determining factor in the calcification of necrotic tissue. In such cases the material can be liberated not only from the nucleus into the cytoplasm but it can leave the cell after its disintegration and pass into the surrounding tissue with its nucleating properties intact. This may explain the numerous calciumpositive granules of basophilic material found in necrotic tissue, which did not in any way resemble nuclei. believe that nucleating compounds from cell nuclei, active in vitro and in vivo, may be very important not only

for the deposition of calcium in necrosis but also in other cases of calcification.

Mobilization of Lymphocytes from Lymph Nodes and Spleen by Polysaccharide Polysulphate

One of us has reported the production of lymphocytosis by polysaccharide polysulphates in experimental animals1. Maximal lymphocytosis was observed 3 h after administration of sulphated polysaccharides, and so lymphocytosis seems to be caused by the mobilization of lymphocytes from storage. The investigation described here was carried out to find the place or places from which the lymphocytes are mobilized into the circulating blood.

Fig. 1. a, Lymph node from a rat given dextran sulphate ($\times 22.5$), b, Lymph node from control rat ($\times 22.5$). Note the depletion of lymphocytes in a in contrast with the appearance of "fullness" in b.

Fig. 2. a, Spleen from rat given dextran sulphate (×6). b, Spleen from control rat (×6). Note the lightly stained periarterial areas in a in contrast with the darkness of the same areas in b. An increase in dark nuclei in the red pulp can also be recognized.

Adult female rats weighing 150-200 g were kept in stress-free conditions for 5 days and starved overnight before the experiments, which were all carried out at about the same time of day to avoid diurnal variation in the leucocyte count. Dextran sulphate with a molecular weight of about 5,000 and a 19 per cent sulphur content was dissolved in sterile physiological saline to give a concentration of 25 mg/ml. and it was injected intraperitoneally into the rats in a dose of 0.2 ml./100 g body weight. Control rats were injected intraperitoneally with the same volume of physiological saline. Preliminary experiments showed that maximal lymphocytosis was obtained 3 h after intraperitoneal injection of dextran sulphate, and so the rats were anaesthetized 3 h after administration by an intraperitoneal injection of sodium pentobarbital (7 mg/100 g body weight) and blood samples were collected by cardiac puncture for leucocyte count and differential count. At the same time tissue specimens were collected. One part was subjected to ordinary histological examinations, and the other part was analysed for DNA content, by a modification of the Schmidt-Thannhauser-Schneider method to compare the number of cells contained in the normal and treated tissues. In all rats injected with dextran sulphate a marked lymphocytosis between two and six times the normal lymphocyte count was observed in circulating blood.

The results of the DNA analysis are shown in Table 1. A marked decrease of DNA after the administration of dextran sulphate was observed only in lymph nodes, while there was a marked increase in circulating blood and a slight increase in lung and spleen.

As shown in Figs. 1 and 2, marked reduction of lymphocytes was noted histologically in lymph nodes and white pulp of spleen after the dextran sulphate had been given. In the spleen (Fig. 2) while lymphocytes were depleted from the periarterial areas of white pulp, a considerable increase in number of lymphocytes was seen in the red pulp in a rather blotchy pattern. This increase seemed to be more than just a reflexion of lymphocytosis in circulating blood. This finding may account for the fact that the DNA content in the spleen of animals injected with dextran sulphate was not lowered as in the lymph nodes. The thymus showed no recognizable change after adminis-

tration of dextran sulphate, which coincides with the result of DNA measurement. The observation supports the view that the thymic lymphocytes differ from lymphocytes in the other lymphoid tissues².

These results show that the mobilization of lymphocytes from lymph nodes and spleen is the chief mechanism of the lymphocytosis in peripheral blood after the administration of dextran sulphate.

pP_y : a Measure of Potentiating Activity

THE absence of a generally applicable pharmacological method for estimating the potency of potentiating compounds such as anticholinesterases and antiamine oxidases is perhaps partly a result of the accuracy with which these compounds can be assayed by manometric techniques on isolated enzymes. Inhibitory potency determined in this way, however, is not necessarily indicative of the potentiating activity to be found in the whole animal or even in isolated tissues.

This communication describes the determination of pP_y values. pP_y , analogous to pA_x (ref. 1) is defined as the negative logarithm of the molar concentration of a potentiating drug which increases the response of a fractional dose (y = 1/x) of agonist to that of an initial submaximal dose. The term pSx has been used previously^{2,3} in a similar context.

The test preparation was the isolated rectus abdominis muscle of the frog; the agonist was acetylcholine placed the muscle bath, which contained oxygenated frog Ringer solution, for 60 sec in each 5 min cycle. The potentiating drug (an anticholinesterase) added to the bath 2 min before the first fractional of acetylcholine and immediately usually for twelve cycles (57 min contact), after each double wash. To obtain pP_y values, different concentrations of anticholinesterase were applied to the right and left muscle, respectively, and then, after a suitable recovery period, each muscle received the alternative concentration. Ideally this enabled four estimations of pP_y to be made on one pair of muscles (Fig. 1), but because of its irreversible action only the first procedure was possible with dyflos.

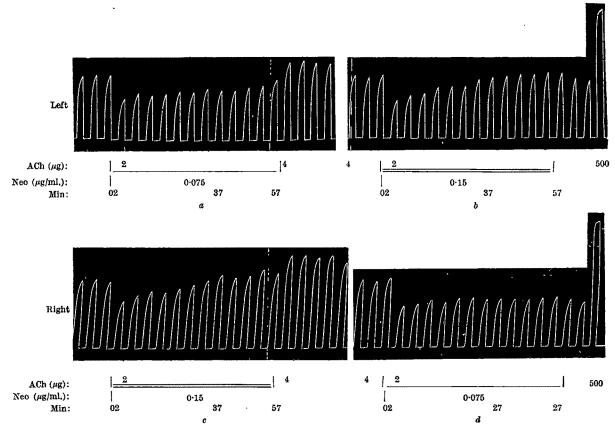

Fig. 1. Frog rectus abdominis muscle in 4 ml. bath. Acetylcholine chloride (ACh) contractures induced every 5 min. ACh doses shown only when changed. Top, left muscle; bottom, right muscle. Between (a) and (b), and (c) and (d), 25 min (five cycles). At _____, 0.075 \(mu g/ml.\), and at \(\begin{array}{c} \begin{array}{c} \begin

Yoffey, J. M., and Courtice, F. C., Lymphatics, Lymph and Lymphoid Tissue, 28 (Harvard University Press, 1956).

Because the initial control response to acetylcholine varied about the 50 per cent maximum response in different experiments, dose-response experiments were performed with edrophonium (four experiments) and eserine (two experiments) to test for linearity and parallelism over the dose-response curve. Three-dose latin square experiments were performed before, during and, in the edrophonium experiments, after the presence of the anticholinesterase. The acetylcholine dose ratio was 4. In only one out of six experiments was there a significant deviation (P < 0.01) from parallelism although in two other experiments there was a significant difference (P < 0.05 and < 0.01, respectively) in quadratic curvature. Inspection of the data and graphs suggested that the significance of these factors would have lessened if a smaller dose-response range had been selected.

Table 1. pP_2 values of anticholinesterases on contractures of the frog rectus abdominis muscle induced by acetylcholine

Compound	Contact time (min)	pP ₂ ± standard deviation (No. of experiments in brackets)	Limits of error $(P=0.05)$ as percentage of mean pP_z	Previously quoted pSx values ^{2,3}
Escrine	17 27 37 57	$5 \cdot 29 \pm 0 \cdot 06$ (3) $5 \cdot 46 \pm 0 \cdot 09$ (8) $5 \cdot 55 \pm 0 \cdot 14$ (18) $5 \cdot 56 \pm 0 \cdot 11$ (12)	± 4·3	6.3
Neostigmine	17 27 37 57	6.34 ± 0.02 (2) 6.49 ± 0.04 (4) 6.49 ± 0.12 (8) 6.52 ± 0.11 (10)	± 3·7	6.28
Edrophonium	2 7 17 57	5.84 ± 0.28 (8) 5.56 ± 0.61 (7) 5.45 ± 0.70 (8) 5.76 ± 0.17 (9)	± 6·6	5-44
Dyflos	117 177	1·35±0·18 (5) 4·43±0·15 (5)	± 8.8	0 44

 pP_2 values of four commonly used anticholinesterases are shown in Table 1. The standard deviations of equilibrium pP_2 values ranged from 0.11 to 0.17 and the limits of error ($\tilde{P}=0.05$) from 3.7 to 8.8 per cent, results which are similar to those found for pA_2 estimations^{1,4}. Table 1 shows both differences in potency and differences in the time required to reach equilibrium conditions. Neostigmine, the most potent compound in this series $(pP_2 = 6.5)$, attained its maximum effect after 27 min, whereas eserine required contact for 37 min and was about nine times less active ($pP_2 = 5.55$). Edrophonium ($pP_2 = 5.8$) showed its maximum effect after contact for only 2 min, the pP_2 values after 2 and 57 min not differing significantly. At intermediate times there was greater variability in the

values. The pP2 values and their equilibrium times for neostigmine and edrophonium agree closely with previously quoted pSx values although my value for eserine seems relatively less active2. These authors also found a close correlation between acetylcholine potentiating activity and IC_{50} values for neostigmine $(0.5 \times 10^{-5}$ molar) and eserine $(1.4 \times 10^{-5} \text{ molar})$ on frog rectus acetylcholinesterase. Dyflos required 2-3 h to exhibit its maximum effect, insufficient potentiation being obtained after contact for 57 min with the concentrations used to obtain pP_2 values. This compound was about thirteen times less active than eserine. Because the molecular weight of dyflos, the slowest acting and least potent compound tested. is similar to that of edrophonium, which achieved its maximum effect very rapidly, it is obvious that diffusion to the site of action is not an important factor in the action/time relationship of these compounds in this preparation. Three estimates of pP_8 were also obtained with eserine $(pP_8 = 5.07 \pm 0.17)$ although the concentrations necessary were such that in other

experiments reduction of the response followed an initial period of potentiation. This accords with previous findings. $pP_2-pP_8=0.49$ for this compound shows that a four-fold decrease in agonist concentration is compensated by a 3·1-fold increase in eserine concentration.

The method is currently being used in a systematic study of the possible acetylcholine potentiating activity of anti-adrenaline compounds.

Tea and Atherosclerosis

MANY people have pointed out a relationship between atherosclerosis and serum lipids¹⁻⁴. Little *et al.*⁵ showed that the concentration of serum lipids is positively correlated with coffee drinking, but slightly negatively correlated with tea drinking. Pauls reported that people who developed coronaries drank more cups of coffee than those without coronaries. Snapper' stated in his book that there was little atherosclerosis in the Chinese, who drink tea almost exclusively.

The absence of atherosclerosis in the Chinese, the Bantus of South Africa, the Negroes in Central Africa and the Yemenites in Asia Minor has been attributed to low contents of serum lipids. Similarly, it should be noted that the cholesterol of the Chinese was lower than that in Europeans or Americans⁹. The work reported here was undertaken to explore the relationship between tea drinking and atherosclerosis.

During the past decade we have developed a quantita tive method of grading the degree of atherosclerosis10. and by this system we can determine the degree of

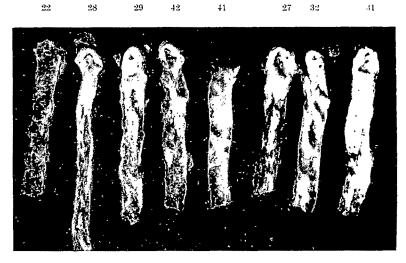

Fig. 1. Aortae from rabbits fed with different ingredient as indicated in each case below: No. 22, control, rabbit chow and water; Nos. 27, 28 and 29, 3 per cent Wesson oil, 0.5 per cent cholesterol and water; Nos. 41 and 42, 3 per cent Wesson oil, 0 per cent cholesterol and tea; Nos. 31 and 32, 3 per cent Wesson oil, 0.0 per cent cholesterol and tea; Nos. 31 and 32, 3 per cent Wesson oil, 0.5 per cent work of the control of the cholesterol and water for 3 months and then water was replaced by tea for another 2 months. Tea was made by boiling 1 g of tea leaf in 2 l. of water and filtered through a filter paper.

atherosclerosis at different segments and even the same segment of the different sectors. Table 1 shows that the overt coffee drinking population has a higher degree of atherosclerosis than the overt tea drinking population.

When rabbits were maintained for 3 months on a diet consisting of rabbit chow augmented with 3 per cent Wesson oil and 0.25 per cent cholesterol, they readily developed atherosclerosis¹¹. Fig. 1 compares aortae from rabbits drinking different beverages. The degree of atherosclerosis is much lower in the rabbits drinking tea than in those drinking water. It is evident that tea seems to protect the aorta from forming atheroma.

Table 2 shows the relationship between atherosclerosis and serum lipid concentration of the experimental rabbits. The concentration of lipid seems to correspond well to the degree of atherosclerosis. The control group had a smaller concentration of serum lipoproteins and there was virtually no atherosclerosis. Rabbits which were given a diet with a high fat content and water to drink showed sclerosis. Rabbits given a diet with a high fat content and water containing the ophylline at a concentration of 10^{-5} g/ml. showed slightly less sclerosis.

Table 1. Degree of atherosclerosis in habitual coffee drinkers and habitual tea drinkers

Population	Coronary artery $(I/E)c^*$	Cerebral arter: $(I/E)\iota^*$
Coffee drinkers	58 (155)†	33 (150)
Tea drinkers	37 (50)	12 (40)

These data were accumulated during the past 14 years of investigation of human coronary and atherosclerosis. The coffee drinkers were Americans (Caucasian) and the tea drinkers were Chinese. • $(IE)_c$, coronary atherosclerosis; $(IE)_c$, atherosclerosis of the brain, where I is intima material area, E is total arterial cross-section, c is coronary artery, and h is brain.

artery, and b is brain.
† Numbers in parentheses are numbers of cases studied.

Table 2. RELATIONSHIP BETWEEN ATHEROSCLEROSIS AND THE CONCENTRATION OF SERUM LIPOPROTEINS IN RABBITS

	Sf 0-12	Lipoproteins 12-20	20-100	Degree of atherosclerosis
Control (6) Diet alone (5) Diet and theophylline (10)	50 309	16 251	0 623	0 7·2 6·5
Diet and tea (4) Diet*early and tea later (10)	$\frac{214}{374}$	79 1 69	437 389	2·0 6·0

* Numbers in parenthesis represent the number of rabbits investigated. † Diet started 3 months before tea was supplied in the drinking water.

On the other hand, rabbits which were given a diet with high fat and tea to drink had much less sclerosis than either of the other groups. The group given only the diet with high fat content for 3 months, and then maintained on the diet and tea regimen for another 2 months, showed less sclerosis than those rabbits given the high fat control diet. These data show that tea decreases concentration of lipids in the serum as was reported earlier^{5,12}. They further suggest that if the atherosclerosis proceeds beyond a reversible stage, tea cannot reverse it. Probably tea must be supplied simultaneously with fat or immediately after a meal of fat. Theophylline and theobromine are far less effective, if at all, than tea in protecting the aorta from forming atheroma. Thus it seems that some active principle other than theophylline in the tea extract must be responsible for preventing the formation of atheroma.

This work was performed under the auspices of the US Atomic Energy Commission.

CYTOLOGY

Growth of the Pre-erythrocytic Tissue Stages of Plasmodium berghei in Isolated, Perfused Tree Rat Liver

RECENT improvements in the maintenance of isolated organs in perfusion systems1-4 suggested that these techniques could be used to study certain pathogens which need a specific cellular environment and an organ of choice. The malaria parasites of man and all other mammalian plasmodia undergo a primary development cycle in the parenchyma cells of the liver of their hosts before invasion of the blood takes place. We thought therefore that successful growth of the tissue phase of the malaria parasites (commonly known as pre-erythrocytic schizogony) in isolated, perfused liver could shed some light on the nutritional requirements of plasmodia during their initial growth in the body and be of use in studies of chemotherapy and immunity. We now report the successful growth of the pre-erythrocytic tissue stages of Plasmodium berghei in isolated, perfused tree rat liver.

We used the liver perfusion-aeration apparatus designed by Professor Leon H. Miller (Department of Biochemistry, University of Rochester) and produced commercially by Metaloglass, Inc., which consists of a thermoregulated plastic chamber in which the perfusion fluid is moved through the glass and plastic tubing by a peristaltic action pump. Oxygenation of the perfusion fluid is regulated by manometric valves in the reservoir cylinder (Fig. 1). The apparatus was sterilized by filling the entire assembled system with an antiseptic solution of 'Ioclide' (Clay

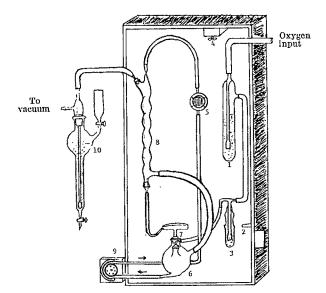

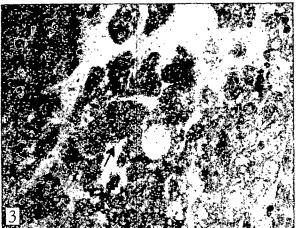

Fig. 1. Liver perfusion-aeration apparatus (drawn from Bulletin M81-B, Metalogiass, Inc.). 1, Humidifier; 2, thermoswitch; 3, gaseous manometer; 4, fan; 5, filter; 6, blood reservoir; 7, liver platform; 8, gaseous exchange tube; 9, pump; 10, carbon dioxide trap.

Adams Co., New York) for 18 h and rinsing several times with sterile water, sterile saline and finally with sterile Ringer's solution. The removable liver platform was sterilized separately in the autoclave. An adult male tree rat (Thamnomys surdaster) from our laboratory colony⁵ was injected intravenously with 60,000 sporozoites of P. berghei. Twenty-three hours after sporozoite inoculation the tree rat was anaesthetized and 100 U.S.P. units of heparin was administered. Laparotomy was immediately performed and plastic tubing (P.E.10, Clay Adams Co.) inserted into the portal vein and into the superior vena cava. All other adjacent vessels were ligated and the inflow and outflow of fluid ascertained by slow flushing with warm heparin-Ringer solution (37° C). Hepatectomy was then performed and the isolated liver attached to the perfusion-aeration system. The perfusion medium was similar to that employed by Folkman et al.6. Its constituents were as follows: Eagle medium ($\times 10$ conc.), 100 ml./l.; calf serum, 250 ml./l.; haemoglobin (human), 1.0 g per cent; amino-acids (×50 conc.), 20 ml./l.; L-glutamine, 2 mmoles/ml.; glucose, 250 mg per cent; aqueous insulin, 0.25 units/ml.; ampicillin, 0.4 mg/ml.; polymyxin B, 100 units/ml., HCl to pH 7.3; sterile distilled water to 11. The liver was perfused for 26 h to permit maturation of the tissue schizonts (a cycle of 48-51 h). It was then removed, cut and fixed in Carnoy's solution, sectioned and stained in Giemsa colophonium. Microscopic examination revealed a number of mature and bursting pre-erythrocytic schizonts in the parenchyma cells. The tissue schizonts showed all the characteristics observed and described in infections in tree rats induced by sporozoites7-8 (see Figs. 2 and 3).

Mature pre-erythrocytic tissue schizonts of Plasmodium berghei showing merozoites. Stained sections from liver of tree rat TR164 maintained in perfusion-aeration apparatus for 26 h. Polaroid land camera, \times c. 285.

We are continuing work on the growth of the tissue stages in the isolated perfused liver of natural and experimental rodent hosts of P. berghei.

We thank Mr Jerold Sklarsh for assistance. This work was carried out under the sponsorship of the Commission on Malaria, Armed Forces Epidemiological Board, and was supported by a US Medical Research and Development Command contract and by a grant from the World Health Organization.

Incomplete Inhibition of Synchronized Cell Division by Hydroxyurea and its Relevance to the Normal Cellular Life Cycle

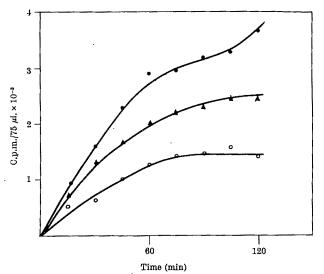

ONE of the more puzzling aspects of synchronized cell division in heat-treated Tetrahymena has been the relative asynchrony of DNA synthesis which persists following the synchronizing treatment. This phenomenon has been well documented in the past and is perhaps most simply demonstrated by the fact that only about 50 per cent of the cell nuclei label with thymidine between the end of the heat-treatment (EHT) and the first synchronous division (SD)¹. Because spectrophotometric measurements of the DNA content of EHT cells have shown that they contain two to three times the DNA found in an average log cell², the reasons for additional DNA synthesis after EHT have been even more obscure. In the past it has usually been suggested that DNA replication is complete at EHT and that this further synthesis in some cells merely represents redundant DNA accumulation by "mature" nuclei3 known to be polyploid4.

We have recently employed hydroxyurea in an effort to study this problem quantitatively. Hydroxyurea was chosen after a search for an antibiotic which would effectively inhibit DNA synthesis in the absence of a sig ifficant effect on RNA synthesis. The other inhibitors examined—for example, phleomycin, mitomycin c, cytosine arabinosides and fluoro-uridine deoxyriboside—all showed a substantial inhibition of RNA synthesis at levels producing the desired inhibition of DNA synthesis. Because the synthesis of RNA5, and particularly mRNA $^{6.7}$, is thought to be necessary for synchronized division in Tetrahymena pyriformis, significant inhibition of RNA synthesis would obscure the meaning of the experiment. To study the effect of hydroxyurea on DNA synthesis we added varying amounts of the drug to 2.0 ml. samples of a 12.0 ml. synchronized culture containing 100 μ c. of ³H-thymidine. In each case, the kinetics of synthosis were followed using the direct filter paper disk procedure which allows better quantitation than autoradiography. The effects of the two higher concentrations (500 and 1,000 μg/ml.) are seen in Fig. I. At 1,000 μg/ml. synthesis is completely inhibited after a lag period during which the

cells are capable of synthesizing about one-half the DNA attained in the control culture at the time of division (compare with Fig. 2). Lower levels of hydroxyurea than those shown resulted in minor degrees of inhibition. Cell viability was unimpaired at even the highest levels. Parallel experiments using ¹⁴C-amino-acids and ³H-uridine gave less than 5 per cent inhibition after 60 min. therefore chose $1,000 \mu g/ml$. hydroxyurea and studied its effect on the kinetics of synchronized cell division.

In Fig. 2 the cell counts obtained from a control culture and one containing 1,000 μg/ml. hydroxyurea are shown. All cell counts are the average of four values obtained at 15 min intervals using a model B Coulter counter. It may be seen that approximately 50 per cent of the treated cells fail to divide even once and the remainder show no further division after the first cycle. It is of particular interest that the number of cells completely inhibited (about 50 per cent) corresponds very closely to the number which ordinarily show nuclear thymidine labelling by autoradiography. In view of the good specificity of the action of hydroxyurea and the close correspondence between the percentage of inhibited cells and the percentage which will usually label with thymidine, it seems reasonable to conclude that the effect of hydroxyurea is based on its ability to inhibit DNA synthesis. It would therefore seem that despite the relatively large stores of DNA in these cells (compared with log cells) further replication is needed. The source of the delay in division induced in the treated cells which divide successfully is not as yet known.

These experiments are therefore consistent with the hypothesis that the small amount of DNA synthesis which occurs in about half the population of synchronized Tetrahymena is nevertheless essential for division in this fraction of the culture. Perhaps the most straightforward interpretation of these results is that the replicating DNA fraction codes for division-related proteins. Because the entire population can be prevented from dividing by actinomycin D^5 and is known to require mRNA synthesis during the early part of this period6,7, it is also possible that actual replication of this DNA fraction is necessary for its transcription to occur. The well documented polyploid nature of the *Tetrahymena* macronucleus⁴ strongly reinforces this latter interpretation because it

Time (min)

Fig. 1. Uptake of ³H-thymidine by synchronized Tetrahymena pyriformis GL. 100 µc, of ³H-thymidine was added to a synchronized culture and the culture divided into six equal portions in flasks containing sufficient hydroxyurea to yield 0, 1, 10, 100, 500 and 1,000 µg/ml. After removal of zero time controls the kinetics of uptake were followed in each flask using the filter paper disk assay. Shown here are the curves obtained from control (—●—) flasks and those containing 500 (—▲—) and 1,000 (—○—) µg of hydroxyurea/ml. Inhibition occurred with all values of hydroxyurea and was complete after a lag in the flask containing 1,000 µg/ml. It may be noted that the total synthesis attained with 1,000 µg/ml. approximates one-third that seen in the conrol at the time of synchronous division (about 90 min).

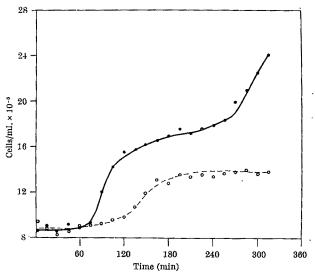

Fig. 2. Kinetics of synchronous cell division in the presence of hydroxyurea 1,000 μ g/ml. Approximately 95 per cent of the control culture has divided by about 90 min (— —). The culture containing hydroxyurea (—)—) shows division by about 50 per cent of the cells after a short delay. Following the first division no further increase in cell number is seen with hydroxyurea while logarithmic growth is resumed in the control flask.

eliminates the problem of gene dosage. Extensive morphogenetic studies have shown that the entire synchronized population is well advanced in the life cycle. These experiments are therefore also consistent with the hypothesis that replication of some division-related genes occurs late in the life cycle. These experiments suggest at least two possible interpretations. The first and most intriguing possibility is that a unique replicating site or sites may exist which is potentially capable of controlling cell division. Failure to replicate and transcribe this site might repress expression of division-related genes. Demonstration of such a site by more rigorous means would have great relevance to differentiation and malignancy. A second alternative, however, is that the cell possesses some recognition system which allows the physical processes of division (for example, mitosis, amitosis or cytokinesis or both) to proceed only when the entire genome has been copied (the late replicating sites not necessarily coding for division-related proteins). If this is the case, then the cells labelling under the conditions described may represent a portion of the mass population which has not yet completely copied their gene complement. We are now conducting experiments designed to distinguish between these two possibilities.

We thank Miss C. Lippincott and Miss W. Jenkins for technical assistance. The hydroxyurea was supplied by Dr B. Stearns of the Squibb Pharmaceutical Co. The work was supported by the US Public Health Service and a special grant from the California Division of the American Cancer Society. One of us (J. E. B.) is currently supported by the US Public Health Service.

MICROBIOLOGY

Inhibition of Haemaggregation by Lepromin and Other Mycobacterial Substances

Human erythrocytes suspended in glucose buffered at about pH 5–5·8 may aggregate and this aggregation can be detected by the rapid settling of cells in a tube or by the pattern of deposit in a tube or plastic haemagglutination plate. The haemaggregation is inhibited by sodium chloride and quite specifically by polioviruses, by influenza viruses¹ and by other biologically active substances including nucleic acids, mucoproteins, tuberculin and rhinoviruses². Old tuberculin and purified protein (derivative) inhibit the haemaggregation of untreated erythrocytes, but certain viruses inhibit only erythrocytes treated with trypsin. The inhibition caused by tuberculin is correlated with skin sensitizing activity and is inhibited by specific antibody³.⁴.

In view of the shortage of in vitro methods for detecting the biologically active components of Mycobacterium leprae and related organisms we have attempted to show

that they inhibit haemaggregation.

The materials for assay were dialysed against a mixture of distilled water and ion exchange resins to remove sodium chloride, and included the following: (a) four samples of integral lepromin prepared from the skin nodules of patients with lepromatous leprosy by Wade's modification of the Hayashi-Mitsuda method⁵, standardized to contain 1.6×10^{8} acid fast bacilli/ml.; (b) washed bacilli of M. lepraemurium, and attenuated M. tuberculosis strain H37 Ra; (c) cytoplasmic fractions of M. leprae, M. lepraemurium and M. tuberculosis (H37 Ra), obtained by rupture of washed bacilli in a French press or Mickle disintegrator and removal of cell walls by centrifugation; (d) washed cell walls of M. leprae, M. lepraemurium and M. tuberculosis (H37 Ra); (e) normal human skin prepared as (a), containing no acid fast bacilli. The materials and methods of the haemaggregation-inhibition plate test have been described in detail². For this study, fresh human group A erythrocytes were used throughout, because they gave clear patterns and high titres. The erythrocytes could be used for 3 days after venipuncture, and were treated overnight with 0·1 per cent trypsin in saline during the night before use and suspended in 0.454 molar glucose. Using WHO pattern plastic haemagglutination-inhibition trays the materials were diluted serially in 0.3 ml. volumes of buffer. Borax-succinic acid buffers were made with varying proportions of 0.1 molar stock solutions of borax and succinic acid—for example, 45 ml. of 0·1 molar borax and 55 ml. of 0.1 molar succinic acid for a solution of pH 5.5—but each mixture was checked and adjusted to the desired pH using a glass electrode pH meter. buffer for dilution was made up just before use by mixing 2 volumes of 0.908 molar glucose, 2 volumes of 0.1 molar succinic acid buffer and 1 volume of 0.375 per cent bovine serum albumin in 0.67 molar phosphate buffer pH 7 which had been heated at 56° C for 30 min and stood at room temperature for 60 min immediately before mixing. The value of heated albumin in obtaining clear patterns and reproducible results is emphasized. To each cup was added 0.2 ml. of a I per cent suspension of human erythrocytes treated with trypsin and the plates were placed at 4° C for 1 h. The patterns were recorded. On each day of assay a control test was performed using sodium chloride -1.125 g of sodium chloride dissolved in 100 ml. of 0.67 molar phosphate buffer-to inhibit haemaggregation. Triplicate cups with a range of buffers from 5.0 to 5.7 with and without sodium chloride indicate the highest pH at which definite inhibition of haemaggregation is observed (Fig. 1). From this control test it may be concluded that aggregation is incomplete at pH 5.6, and that it is completely inhibited between pH 5.4 and 5.6.

Table 1. Inhibition of haemaggregation by mycobacterial substances and normal skin

Source	Organism	Preparation	Titre
Human lepromatous skin	M. leprae	Lepromin Mitsuda (1963)	*1,280
Human lepromatous skin	M. leprae	Lepromin Mitsuda (Japanese)	1.280
Human lepromatous skin	M. leprae	Cytoplasmic fraction	3,200
Infected rat liver	M. lepraemurium	Washed bacilli	80
Infected rat liver	M. lepraemurium	Cell walls	80
Infected rat liver	M.lepraemurium	Cytoplasmic fraction	160
Culture	M. tuberculosis (H37 Ra)	Washed bacilli	80
Culture	M. tuberculosis (H37 Ra)	Cell walls	20
Culture	M. tuberculosis (H37 Ra)	Cytoplasmic fraction	1,024

* This material agglutinated red cells to a titre of 320.

The results of a typical test are set out in Fig. 1 which shows that at the optimum pH of 5.6 the cytoplasmic fraction of M. leprae tested had an inhibitory titre of 1/3,200. It can be seen that it is important to use the optimal pH. It was also shown that the same titres were obtained with cells of blood group O and A, but that titres were up to four times higher or lower if the cells were not treated with trypsin; but the mean difference between titres of nine comparisons was zero. No inhibition of haemaggregation was seen with horse cells, and rat cells were too unstable to use. Further materials were tosted and some representative results are shown in Table 1. Several different mycobacterial preparations were active. The cytoplasmic fraction of M. tuberculosis was much more active than the cell wall preparation and whole bacilli; but less difference was observed between the cytoplasmic fraction of M. lepraemurium and washed bacilli and cell walls. An extract of normal skin was prepared, but agglutinated red cells too strongly for use in the test.

Because haemaggregation was inhibited by both crude skin extracts and highly purified bacilli and their products, it seems probable that the activity of lepromin preparations is caused by a component of the leprosy bacillus, although further proof is necessary. It may be possible to show, as

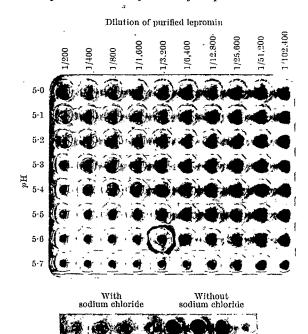

Fig. 1. The appearance of a representative test. The lower part shows that haemaggregation at three pHs has been inhibited by sodium chloride. The upper plate shows that serial dilutions of purified lepromin have inhibited haemaggregation; the highest titre is seen using the most alkaline buffer and the cup showing the end point is marked by a ring.

has been done in the case of tuberculin, that the inhibitory titre is proportional to the skin reacting activity, and also to adapt the test for the measurement of antibodies. This preliminary report is made so that others who may be able to obtain suitable material can explore the significance and possible applications of the phenomenon.

Isolation of Cyanophages from India

Using the methods of Safferman and Morris¹, who isolated the first phycovirus, strain LPP-1, and propagated it on the blue green alga, Plectonema boryanum, five strains of cyanophages2 have been isolated from local polluted pond Two of these differ in host range and plaque morphology while the remaining three bring about lysis of LPP-1 host, P. boryanum, although showing variation in growth behaviour and plaque size. The first two strains infect either spore forming and/or heterocystous blue green algae and are inactive on P. boryanum. One of these which has been isolated on a species of Cylindrospermum, forming heterocysts at both ends of its filaments and subterminal chains of spores, has a restricted host range. It does not infect other strains of Cylindrospermum with a similar morphology or Anabaena doliolum, another heterocystous and spore forming blue green alga. The second isolate causes lysis of three spore forming blue green algae, Anabaenopsis raciborskii, A. circularis and Raphidiopsis indica, of which the first two are also heterocystous. The first isolate is designated C-1 and the second AR-1 following the terminology of Safferman and Morris¹ for LPP-1, which is based on the first letter of the genus name of the host algae. Strain C-1 causes fast lysis of the host in liquid medium and on agar plates. Plaques appear late but their size increases very fast and the entire algal growth on the plate is lysed within a few days. AR-1 plaques are irregular in comparison with LPP-1. Their size increases with longer incubation. After 16 days plaque size varies from 5 mm to 14 mm (Fig. 1). The margin of the plaque is frayed because of the filamentous nature of the host algae. The notable characteristic of strains C-1 and AR-1 is that they do not lyse spores and heterocysts which remain unaffected in plaques or lysates (Figs. 3 and 4). The gas vacuoles of the algae possessing them also remain unaffected by the strain

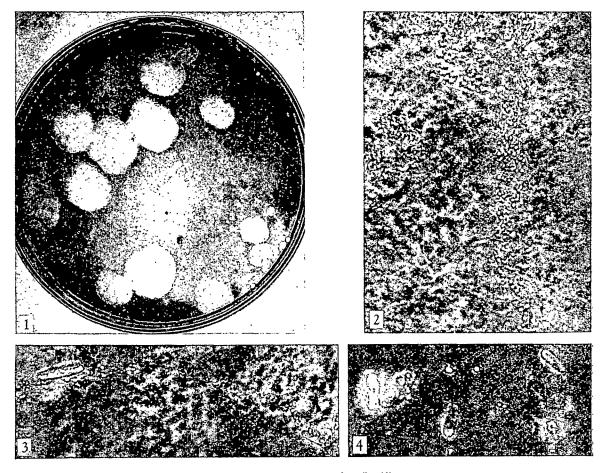

Fig. 1. Plaques of Anahaenopsis racihorskii.

Figs. 2-4. Photomicrographs of lysates. (×800, phase optics.)

Figs. 2-3. Anahaenopsis circularis showing trails of unlysed gas vacuoles and spores.

Fig. 4. A. racihorskii showing unlysed heterocysts and gas vacuoles.

AR-1, leaving trails of gas vacuoles behind (Figs. 2, 3

The isolates on P. boryanum have been designated P-2, P-3 and P-4 on the basis of their restricted host range and differences in plaque morphology and growth behaviour in comparison with strain LPP-1. The size of plaques in P-2 is large (8-12 mm after 12 days) and the host is lysed in about 4 days. Lysis occurs late with P-3 and P-4 and size of plaques varies from 1 mm to 4 mm after 12 days. Lysis with these isolates as with LPP-1 is Cyanophage LPP-1 resistant strains of P. boryanum (our unpublished results) are not resistant to viral isolates P-2 and P-3.

Safferman and Morris³ screened a large number of blue green algae including heterocystous and spore forming genera, Anabaena, Anabaenopsis, Cylindrospermum, Nodularia, Nostoc, Fremyella, Calothrix and Tolypothrix with their BGA virus strain LPP-1, and found it to be inactive. It is therefore the first report of isolation of cyanophages active on heterocystous and spore forming blue green algae. Besides raising questions of taxonomic grouping of these algae their behaviour towards the cyanophages C-1 and AR-1 provides thought to the basic problems concerning the nature of enigmatic structures like heterocysts and gas vacuoles and reproductive structures like spores, which remain unaffected by these viruses. These structures are also insensitive to lysozyme (our unpublished results). The chemical composition of their walls seems therefore to be different from the walls of ordinary vegetative cells which are dissolved by treatment with lysozyme. The other possibility is that DNA of heterocysts and spores may be in a non-replicative state and their metabolic inactivity suggests that they are insensitive to the virus strains described here.

Integration of Energy Conversion and Biosynthetic Processes in Bacterial **Photosynthesis**

Many species of photosynthetic bacteria can grow in the absence of molecular oxygen (anaerobically) using organic compounds as the sources of cellular carbon1,2. These organisms, however, differ strikingly from nonphotosynthetic anaerobes in that they seem to be unable to obtain sufficient energy for growth from dark fermentative catabolism of organic substrates. Whatever the carbon source, the photosynthetic bacteria seem to require light for multiplication under anaerobic conditions2,3. Through the activity of the photochemical system, light energy is converted to chemical energy in the form of adenosine triphosphate (ATP)^{4,5}, the key fuel for biosynthesis in all types of cells. It is possible that at least part of the energy requirement for anaerobic growth of photosynthetic bacteria can be satisfied by exergonic catabolism of particular substances, but so far this has not been shown. Our search for alternative (dark) anaerobic processes capable of generating ATP at significant rates led us to investigate the intimacy of biochemical coupling between the photochemical energy conversion apparatus and biosynthetic metabolism in the photosynthetic bacterium Rhodopseudomonas capsulatus. The initial aim

was to determine the length of the time period over which the biosynthetic machinery can function at a normal rate following cessation of illumination. The experiments reported here indicate a very tight coupling between the light-dependent ATP generating system and overall biosynthesis, and also describe an experimental approach which should prove useful in exploring the general problem of how energy conversion and biosynthetic processes are integrated.

The initial experiments were based on two assumptions, namely, that: (a) because the photochemical reactions involved are extraordinarily rapids and the subsequent dark reactions associated with ATP formation seem to be completed within only 0·1-0·15 sec (ref. 7), the in vivo rate of ATP production at high light intensity is likely to be fast in comparison with the rates of the enzymatic processes responsible for biosynthesis of cell materials; and (b) during a light period of some particular length, presumably quite short relative to the mass doubling time in continuous light, cells must accumulate sufficient ATP to drive overall biosynthesis at an optimal rate over a subsequent dark period of comparable length. Accordingly, the growth rate with some suitably programmed regimen of intermittent illumination should be equal to that observed in continuous light. Consider now a regimen of equal light and dark times in which the period is much longer than the 'magic' length. It is evident that in these circumstances biosynthesis (growth) will proceed during the light periods, but owing to lack of a continuing energy supply it will be virtually suspended during the dark periods. If growth resumes without lag at the start of each light period and if degradation of essential cell components does not occur to an appreciable extent durin; the dark periods, the overall average growth rate of the cell population should be approximately half the control value. These predictions were tested as follows.

Freshly inoculated cultures of Rps. capsulatus were grown in continuous light until they had entered the logarithmic growth phase. They were then exposed to intermittent illumination, each light period being followed by a dark period of equal length. Growth kinetics with light: dark cycles of different duration were determined by measuring turbidity of the cultures. Typical results showing the relationship of growth rate to length of the light: dark cycle are shown in Table 1.

Table 1. GROWTH RATES OF Rhodopseudomonas capsulatus in continuous AND INTERMITTENT LIGHT

Length of light : dark cycle (sec) 0 (continuous light)	Doubling tim (h) 2·4
10·0 20·0 40·0 60·0 120 240 600 1,200	7·2 9·2 9·0 8·8 8·8 8·8 6·0

A synthetic 0.4 per cent DL-malate + 0.1 per cent ammonium sulphate medium similar to the one specified by Ormerod et al. was used, with thiamine hydrochloride (1 mg/l.) added in place of blotin. Inoculated cultures, in completely filled screw-cap test tubes of 17 ml. capacity, were incubated in continuous light until the bacterial density was approximately 50 Klett-Summerson photometer units (filter No. 68). The tubes were then subjected to repeating light: dark cycles as indicated; in each cycle. light and dark times were equal. Growth rates are given in terms of time required for the bacterial mass to double as indicated by photometer measurements; the shift from continuous to intermittent illumination did not induce a significant lag, and the overall growth kinetics were logarithmic over several doublings. Light source: 30 W reflector flood lamps. Light intensity: 400 ft.-candles (as measured with a Weston Illumination meter model 756), which is essentially saturating; increase of Intensity to 550 ft.-candles decreases the doubling time in continuous light to 2·0-2·2 h. Temperature: approx. 30° C.

It can be seen that even with a cycle as short as 10 sec (that is, 5.0 sec light: 5.0 sec dark), the mass doubling time is significantly longer than the control value of 2.4 h observed in continuous light. The doubling time with even shorter cycles may well approach that of the control more closely, but this has not yet been investigated. Inhibition of growth was particularly pronounced with

cycle lengths between about 20 sec and 4 min, and this range is therefore of special interest. The constancy of the growth rate over this rather wide range suggests that a characteristic lag, occasioned by dark to light transitions, in some critical process is not the primary cause of the inhibition. The expected result with relatively lengthy light and dark periods was not observed with cycles as long as 10-20 min, but a separate series of experiments showed that the doubling time with cycles of 30 min or longer was indeed close to twice that of the control. The data of Table 1 indicate that in Rps. capsulatus there is a very close coupling between the activity of the photochemical energy converting system and the biosynthetic apparatus of the growing cell. It also seems that during photosynthetic growth at high light intensity in a malate + ammonium sulphate medium, the bacteria do not store reserve materials which can be rapidly mobilized to provide energy in the absence of light. The integration between the photophosphorylation system and biosynthesis is evidently markedly disturbed when energy flow is repeatedly interrupted at certain frequencies. From the results of the growth experiments we infer that in the particular medium used, a period of the order of several minutes is required for completion of a key energy dependent process, necessary for optimal balanced growth of Rps. capsulatus. It may be that interruption of energy flow for a significant time during this period is attended by alteration or partial degradation of precursors of a "key product" and that the cumulative effect of such repeated interruptions is an inhibited growth rate.

As a first approach to studying the nature of the derangement caused by intermittent illumination of short cycle, we have analysed cells grown under different regimens for their contents of protein and ribonucleic acid (RNA). With continuous saturating light (550 ft.-candles), the protein/RNA ratio in the cells is about 3. After several mass doublings in intermittent light with cycle lengths between 30 and 120 sec, the ratio increases substantially (for example, to 4.6 with a 60 sec cycle), chiefly because the RNA content decreases significantly. On the other hand, the protein/RNA ratio of cells grown with light: dark cycles longer than 5 min approximates the value characteristic of organisms cultivated in continuous light. This suggests that with longer cycle times, biosynthesis proceeds during the light periods at a nearly optimal rate and is essentially "frozen" during the dark periods. The changes observed in the protein/RNA ratio are doubtless related in some way to the growth rates under the several conditions. It is well known with certain non-photosynthetic bacteria that, over a particular range of doubling times, growth rate (with continuous energy supply) is proportional to total cellular RNA contents. Because the growth rate and ribosome content of the cell are similarly correlated9, inhibition of ribosome synthesis may possibly be one of the major early consequences of interference with energy

Studies¹⁰⁻¹² on a number of non-photosynthetic bacteria of different physiological types have shown that the synthesis of one g dry weight of cell material requires the regeneration of about 100 millimoles of ATP from adenosine diphosphate (ADP) and it is likely that this also holds for photosynthetic bacteria. The size of the steady state pool of adenylate nucleotides (adenosine monophosphate (AMP), ADP, and ATP) present in growing bacteria—for example, about 0.015 millimoles per g dry weight in the photosynthetic bacterium *Chromatium* 13—is clearly insignificant in terms of the energy requirements for net growth and quite small in respect to the amounts necessary for appreciable nucleic acid synthesis. Adenylate nucleotides exert regulatory effects on the activities of a number of enzymes¹⁴ and it is possible that the pool functions primarily as a signal device for control of energy flow and biosynthetic reactions directed toward macromolecular syntheses. Although the total size of the adenylate nucleotide pool may not vary greatly under different

metabolic conditions, recent experiments of Atkinson et al. 15,16 show that the activity of certain enzymes which utilize ATP is strongly affected by changes in the relative concentrations of the nucleotide species. The composition of the pool in Rps. capsulatus subjected to intermittent illumination presumably oscillates between limiting states of high and low "energy charge", a concentration ratio control parameter defined as (ATP+0.5ADP)/(ATP+ ADP + AMP). Other significant oscillations must occur, such as in the ratio reduced/oxidized pyridine nucleotide, and the net effect of intermittent illumination on growth will obviously be the resultant of a number of interdependent changes in a very complex network of biochemical reactions. Experiments now in progress are aimed at evaluating the working hypothesis that operation of the biosynthetic machinery in Rps. capsulatus is dominated by the rate of ATP generation and the "energy charge".

In view of their relatively rapid growth rates and other metabolic properties, and the ease with which the activity of the energy conversion system can be experimentally manipulated, photosynthetic bacteria lend themselves to investigation of a number of general problems, especially the control mechanisms which govern integration of energy yielding and biosynthetic processes. The technique of programmed illumination is essentially a means of pulsing ATP formation in vivo and, as such, obviously can be exploited for study of several important aspects of metabolic regulation.

IMMUNOLOGY

"Species Specificity" of Interferons: a Misnomer?

In 1961, there were two reports of monkey interferon protecting human cells1,2 and one of human interferon protecting monkey cells3, but in none of these was the extent of the cross-reaction measured. In view of the usual strict "species specificity" of interferons (for example, chick interferon is not active in mouse cells, human cells4 or duck cells5), it seemed worthwhile to examine the cross-reactivity of human and monkey interferons.

For our present work, we have used a cytopathic effect-inhibition assay with tube cultures of either diploid human embryo lung cells or primary monkey kidney cells (Erythrocebus patas or Cercopithecus aethiops). The assay tubes were incubated with the interferon for 24 h at 37° C, and the interferon was removed and the tubes were washed twice with fresh medium before challenge. The purpose of this was to remove inhibitors other than interferon which may have been present in the preparations^{6,7}. The challenge virus was 100 TCD_{50} of HGPrhinovirus which had similar growth characteristics in both monkey kidney and diploid human lung cells, and the test was read after 3 days at 33° C. Interferons were prepared by infecting monkey leucocytes (Macaca nemestrina) or human leucocytes with Sendai virus, and collecting the culture fluid after 18 h. Virus was destroyed by keeping the fluids at pH 2 for 5 days, and a potent Sendai antiserum was added before assay.

Four batches of monkey and human interferons were assayed and each gave high heterologous titres (Table 1). With the monkey interferon, the titre in human cells was usually greater than that in monkey cells.

Table 1. THRE OF HUMAN AND MONKEY LEUCOCYTES INTERFERON IN

		110344511 211137	DIOLILLIA CLI	200	
	Monkey i			Human i	
Batch	Monkey cells	Human cells	Batch	Monkey cells	Human cells
1	26	40	1	20	85
2	55	100	2	165	400
3	60	126	3	500	600
4	1,000	1,000	4	3,000	2,000

Monkey interferon was made from leucocytes of Macaca nemestrina. Batches I-3 were assayed on primary kidney cells of Cercopithecus aethiops, and batch 4 on primary kidney cells of Erythrocebus patas. The human cells were embryonic lung.

Using the most potent interferon sample (batch 4), the respective homologous and heterologous activities were shown to be unaffected by low pH, ultracentrifugation and treatment with ribonuclease, but they were destroyed by trypsin. There was some reduction in titres when Sindbis virus was used as challenge, and neither type of interferon showed any activity in mouse L cells (Table 2). From this it seems that the high cross-reactions of monkey and human interferons are genuine heterologous activities.

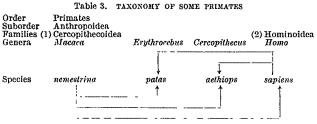

Table 2. THE CHARACTERIZATION OF MONKEY AND HUMAN INTERFERON HETEROLOGOUS ACTIVITIES

The present results show that interferon made from one

genus of monkey-Macaca-is active in cells from two other genera—Čercopithecus and Erythrocebus. monkey interferon does not show "species specificity"

The cross-reaction of interferons is shown by arrows.

or even "genus specificity". These three genera belong to the family Cercopithecoidea (Table 3) and, because interferon from Macaca is active in human cells, and human interferon is active in Cercopithecus and Erythrocebus cells, there seems to be complete cross-reaction at the level of the taxonomic family. Until the extent of this type of cross-reaction is more clearly defined, perhaps it would be preferable to abandon the term specificity" and instead state the cell types in which heterologous interferon activity is or is not known.

Factors influencing Lysis of Whole **Blood Clots**

LITTLE is known about the mechanism by which blood clots or fibrin monolayers usually lyse. The enzyme plasmin (fibrinolysin) has been assumed to play a key part in this mechanism and for this reason plasmin, its substrates fibrinogen and fibrin and its naturally occurring inhibitors have all been extensively studied and characterized1. The biological importance of these studies has depended on the assumption that the plasmin system serves to maintain the homeostatic balance between the polymerization of fibrin and the dissolution of this polymer. Although much is known about the activation of the polymerization phase of this homeostatic system, there is little information about the mode of activation of the clot dissolving or plasmin system in the intact blood clot. We describe here in qualitative terms some of the factors and steps involved in the lysis of a clot from whole blood diluted 1:10 with phosphate buffer2.

A sample (1 ml.) of whole blood was drawn from the antecubital vein of the forearm and immediately diluted 1:10 with phosphate buffer (0.034 molar, μ 0.072, pH 7.4) at 4° C. At this temperature and dilution the sample will not clot spontaneously. Inhibitors, that is, antisera and cobra serum, were then added to the diluted whole blood. Samples (2 ml.) in 15×100 mm test tubes of treated and untreated diluted blood were then coagulated at 4° C by the addition of 1 U of thrombin obtained from Parke-Davis, Detroit, Michigan. After 20 min at 4° C, the clots which formed were transferred to a water bath at 37° C and observed for retraction, shedding of red cells and time of complete lysis.

The requirement of platelets for the lysis of these clots is shown in Table 1. Samples of diluted blood (2 ml.) were centrifuged at 0-1,800g for 10 min before they were decanted into a second tube and thrombin was added at

Table 1. RELATIONSHIP OF RED BLOOD CELL AND PLATELET COUNTS TO CLOT DISSOLVING TIME

4° C. Removal of red and white cells was virtually complete at 200g with no appreciable effect on clot retraction or time of lysis. When the platelet count was lowered to 1,100/mm³, however, retraction was reduced and clot lysis was prolonged. The normal times of clot lysis were restored on resuspension of the platelet buttons. That the platelets have to be structurally intact at least for the initial phase of clot lysis was demonstrated by sonication. Some samples were sonicated 15 min before and some 15 min after addition of thrombin. Those samples in which platelets were destroyed by sonication before thrombin was added did not retract and the lysis time was prolonged from 4 to 14 h. Those samples in which platelets were destroyed by sonication after thrombin was added retracted and lysed normally.

The requirements of plasminogen, YM-globulin and of the third (C'3) and the fourth (C'4) components of complement for normal clot lysis were demonstrated by the inhibition of retraction, shedding of red cells and clot lysis which resulted from the addition of specific antibodies to the assay system. Rabbit antisera to human albumin, α_2 -macroglobulin, transferrin, γG -, γM -globulin and γM cold agglutinin were obtained commercially from the Behringwerke Company, Marburg/Lahn, Germany, and antisera to human plasminogen3, C'3 (ref. 4) and C'4 (ref. 5) were prepared as described previously. The gamma globulin fractions of these antisera were prepared by precipitation with ammonium sulphate according to the method described by Kabat and Mayers. These fractions were made up to the original serum volume and samples of 0.25 ml. were then added to the 2 ml. aliquots of diluted, normal, whole blood 5 min before the addition of thrombin. Table 2 and Fig. 1 show that antisera to γM, C'3, C'4 and plasminogen inhibited clot retraction and lysis, whereas the antisera to albumin, a2-macroglobulin, transferrin and γG -globulin did not affect clot retraction or lysis. A highly purified protein from cobra venom7, which has been shown to inactivate selectively C'3, also caused inhibition of clot lysis. Addition of 20 to 40 μg of homologous antigen—that is, purified γM, C'3, C'4 or plasminogen—to these systems restored normal lysis, provided that they were added before the thrombin. All preparations of the complement components and of γM were tested for plasminogen activity but none was found.

Platelets, γM and complement components seem to be involved in clot lysis in vitro, which suggests that there is a functional association between platelets and these serum factors. In order to examine this possibility, platelets were collected from 10 ml. of whole blood diluted 1:10 with phosphate buffer at 4° C by centrifuging at 700g for 20 min and then collecting the plateletrich supernatant. These platelets were washed twice in phosphate buffer and resuspended in buffer to give a final count of 300,000/mm³. At this concentration there was no platelet aggregation or viscous metamorphosis. A sample (0·1 ml.) of the platelet suspension was mixed with 0·05 ml. of various dilutions of antisera listed in Table 3 and examined for agglutination after 30 min with the aid of a hand lens. A 1:10 dilution of platelets,

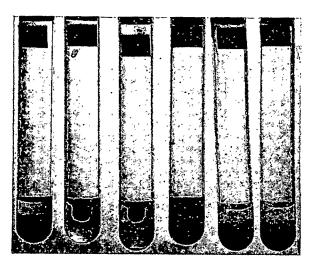

Fig. 1. Diluted whole blood clots. 0·25 ml. aliquots of partially purified rabbit antibodies have been added to: (1) albumin; (2) C'4; (3) C'3; (4) γM; (5) γG; (6) a₃-macroglobulin. Photograph taken 4·5 h after addition of thrombin. Samples 1, 5 and 6 have undergone complete lysis. Samples 2 and 3 have retracted but have shed few red cells and have not lysed. Sample 4 has not retracted, shed red cells or lysed.

whereas a 1:10 dilution and less of antisera to albumin, α_2 macroglobulin and transferrin did not cause agglutination. The antisera to γ G- and γ M-globulins caused 0 to 1+ aggregation, respectively. Purified γ M, C'3 and C'4 inhibited agglutination when added to the antisera before mixing with platelets.

before mixing with platelets. Although γM , C'3 and C'4 seemed to be associated. with platelets, the question remained to be answered whether the complement components were specifically adsorbed onto the platelets and whether they were adsorbed in vivo or in vitro. A 2 ml. sample containing 1×10^{10} platelets was tested for immune adherence by incubation with 0.1 ml. of 1×108 red blood corpuscles from the same subject. Immune adherence to erythrocytes is known to depend on the presence of specifically bound C'3 on the surface of the adhering particles. A 2+ reaction for immune adherence was noted, indicating that at least some of the C'3 was adsorbed specifically and in active form. In answer to the second question, blood platelets, drawn at 37° C and diluted with phosphate-sodium chloride buffer to give an ionic strength of 0.15, were examined for bound C'3 and C'4 by agglutination using specific antisera. In these conditions the agglutination reactions were significantly weaker than those seen with platelets of blood collected at 4° C and diluted in phosphate buffer with an ionic strength of 0.072 (see Table 3). Normal clots and clots to which antibodies to YM-globulin, C'3 or C'4 had been added were processed, sectioned and stained for microscopic examination of the relationship of platelets to the fibrin network. Clots examined 30 min after addition of thrombin revealed platelets adsorbed onto the fibrin strands, whereas the platelets had fused and were no longer discernible as individual elements in clots sectioned 2 h after addition of thrombin (Fig. 2A). The addition of antisera to YM, C'3 or C'4 inhibited fusion of the platelets as shown in Fig. 2B where platelets were still present and intact after 2 h in a clot containing anti- γ M-globulin.

Platelets were washed at	4° C. 40.072, and at 37°	C. u 0.15.

There is a class of acquired haemolytic anaemias which is associated with the occurrence of cold agglutinin in the blood and the presence of C'3, C'4 on the surface of the erythrocytes¹⁰. We studied two of these patients with Dr Hugh Fudenberg of the University of California, San Francisco, and found that they had a short clot lysis time (2 h compared with 4-6 h for normal controls) and markedly positive agglutination reactions of their platelets when these were tested with antisera to \(\gamma M\)-globulin, C'3 or C'4. Patients with low platelet counts (10,000/mm³) were found to have rates of clot lysis twice as slow as normal, whereas patients with high platelet counts (800,000/mm³) had very rapid rates of clot lysis, as seen in studies with Dr Richard Creech of the University of Pennsylvania. One patient with Glanzmanns thrombasthenia (an abnormality of clot retraction and platelet agglutination in presence of adenosine diphosphate) had markedly inhibited clot lysis. The latter study was made in collaboration with Dr M. Zucker of New York University.

In conclusion, the preceding data suggest in qualitative terms what factors might be involved in one mechanism for the lysis of diluted whole blood clots in vitro. tentative concept of the underlying mechanism may be formulated in the form of the following working hypothesis. Platelets of diluted whole blood at 4° C adsorb

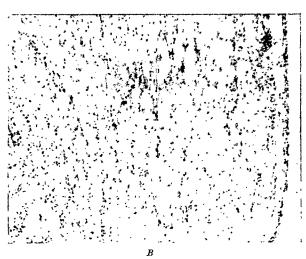

Fig. 2. A, Photograph of diluted whole blood clot 2 h after addition of thrombin. Note that platelets have fused and that there is contraction of the platelet-fibrin elements. B, Diluted whole blood clot with 0.25 ml, of antihuman yM serum 2 h after addition of thrombin. Note that platelets have not fused and that there is no retraction of platelet-fibrin elements.

γM-globulin (possibly 19s cold agglutinin) which triggers a complement reaction involving at least the components C'1, C'2, C'3 and C'4. The platelets bearing these proteins on their surface are then incorporated into the thrombin induced fibrin network, possibly by a reaction which resembles immune adherence. The protein coat may facilitate, if not initiate, fusion of the platelets, and activation of plasminogen may then be caused either by the enzyme activities associated with the complement components on the platelet surface or by enzymes released from the fusing platelets. The possible relevance of the observations made in this artificial system to in vivo and clinical situations is supported by observations on various clinical cases with selected abnormalities including patients with accelerated fibrinolytic states associated with acquired haemolytic anaemia characterized by the presence of cold agglutinins, high YM-globulin levels, 19s cold agglutinins and adsorption of C'3 and C'4 to erythrocytes and platelets under physiological conditions.

We thank Jorene Moore, Ilona Staprans and Rhoda Sheena for their technical assistance and Dr S. Sherry, A. F. Bickford, H. Fudenberg, E. Becker and Mrs E. Corbelli for their encouragement. The work was supported by a US Public Health Service grant and an American Heart Associate grant.

Search for I Antigen in Human Tissues

THE majority of human red cell cold agglutinins have a specificity for an antigen termed I which is present in the red cells of the vast majority of adults1. Only very occasionally does an adult lack the I antigen. The high titre anti-I cold agglutinins found in association with chronic autoimmune haemolytic anaemia and, transiently, in association with Mycoplasma pneumoniae infection are therefore autoantibodies. In human infection with Myco-plasma pneumoniae the cold agglutinin seems to be directed not against the infecting organism but against the host red cell2. The present study was undertaken to investigate whether I antigen can be detected in human tissues other than erythrocytes and hence to determine whether anti-I cold agglutinin is an organ specific or a non-organ specific antibody.

Organ homogenates, prepared from three cases (adults) at post-mortem examination, were tested for their ability to absorb anti-I cold agglutinin at 4° C. Twentyeight organs were examined and sixteen of them were obtained from more than one case (Table 1). The anti-I cold agglutinin used was from a patient with chronic autoimmune haemolytic anaemia; it had been purified by

repeated absorption onto and elution from group OI red cells by a technique previously described and had a cold agglutinin titre of 256 at 4° C. Tissue samples, weighing approximately 10 g, were cut into small pieces with scissors and washed in several changes of normal saline until there was no blood staining of the washings and they were then homogenized in cold saline using a Griffin and George mechanical homogenizer. The organ homogenates were washed twice by suspending them in an excess of normal saline followed by centrifugation at 3,000 r.p.m. for 15 min and 25 per cent suspensions (v/v) of them were made in normal saline. In addition, 25 per cent suspensions were made of washed red cells from (a) each post-mortem case, (b) a healthy adult of group OI and (c) a healthy adult of group Ai (i denotes lack of I antigen). In the absorption tests, 0.4 ml. of each antigen suspension was pipetted into a 1 x 6 cm plastic tube, the antigens were packed by centrifugation at 3,000 r.p.m. for 10 min and the supernatants were removed, leaving in the tubes 0.1 ml of packed antigen, each of which was mixed with 0.4 ml. of anti-I reagent and incubated for 2 h at 4° C. The tubes were shaken at intervals of 30 min. At the end of the incubation period the supernatants were separated after centrifugation at 3,000 r.p.m. at 4° C for 10 min and they were then tested for residual anti-I activity, that is, their cold agglutinin titres were determined by a micro technique which has been previously described2. At the same time, the cold agglutinin titre of unabsorbed anti-I reagent was determined. Each titration was performed in duplicate. The inhibition score for each tissue was the number of "tubes" by which the anti-I titre was reduced after absorption, for example, a score of one indicates a two-fold reduction and a score of two indicates a four-fold reduction in titre. In one of the post-mortem cases (of blood group B) the ability of the stomach homogenate to absorb anti-B was tested using the same v/v ratios of antigen to antibody; an anti-B serum with a titre of 128 was used.

The mean anti-I absorption scores of red cells from the post-mortem cases and from the healthy adult were 4.6 and 4.3, respectively (representing a sixteen-fold reduction in anti-I titre), compared with a score of zero with the i red cells; the mean scores of all the other tissues tested were between zero and one. Because a two- or even a four-fold difference in cold agglutinin titre is within the experimental error of this technique, it is

^{*}Inhibition score denotes number of "tubes" fall in anti-I titre after absorption with antigen at 4° C. Duplicate titrations were performed for each antigen preparation; the mean score was therefore representative of two to six readings.

doubtful whether any absorption of anti-I had occurred with any of the organ homogenates. Furthermore, the incubation of a gross excess of these organ homogenates with anti-I reagent (0.8 ml. of packed antigen with 0.2 ml. of anti-I reagent) did not result in significant change in anti-I titre. The group B stomach homogenate, however, completely absorbed the anti-B antibody from the serum, yielding a score greater than 6. Absorption tests using an anti-I serum from a patient with Mycoplasma pneumoniae infection and homogenates of lung, liver, brain and erythrocytes from one of the post-mortem cases gave results comparable to those in Table 1 (results not shown).

In a further experiment, a search for soluble I antigen in the organs was made by incubating 25 per cent suspensions of the organ homogenates at 4° C overnight and adding 0.2 ml. of their supernates to an equal volume of anti-I reagent. After incubation for 1 h at 4° C there was no loss of anti-I activity, which indicates that there was no detectable I antigen in soluble form. Because I antigen seems to be localized to red cells anti-I cold agglutinins can be considered as organ specific auto-antibodies.

We thank Dr W. J. Jenkins for supplying us with group Ai red cells and Drs P. Scheuer and Anne Stuart for the post-mortem material. This work was supported by grants from the Royal Free Hospital and the Medical Research Council.

Immune Cross-reactivity of Penicillin and Cephalothin

WE recently described positive direct Coombs tests in patients receiving sodium cephalothin. Because most normal sera caused the *in vitro* agglutination of red cells coated with cephalothin, we concluded that some of the positive direct Coombs tests must be related to non-immune binding of a serum protein-cephalothin complex to the red cell surface. We also suggested the possibility that some of these test sera contained anti-penicillin agglutinins.

Despite the similarity in molecular structure between penicillin and cephalothin, very few instances of allergic reactions have been reported among patients known to be allergic to penicillin who were receiving cephalothin²⁻⁴. In patients with a history of penicillin allergy, the association of positive haemagglutination with the more severe forms of allergy is striking, but not absolute⁵. In patients with benzyl-penicilloyl (BPO) specific skin sensitizing antibodies, there is an association with circulating BPO specific antibodies. In normal patients without a history of penicillin allergy, however, and who even have negative skin tests, almost 10 per cent have a significant haemagglutination titre against penicillin treated cells. Furthermore, some patients who have never received penicillin have positive haemagglutination tests7. The correlation between clinical allergy and haemagglutination reaction is not therefore absolute. We have studied the serological cross-reactivity of penicillin and cephalothin in a haemagglutination system.

Red blood cells were coated with penicillin and tests for anti-penicillin agglutinins were done by the method of Ley*: agglutination tests with cephalothin were

performed as previously described1. Eluates prepared by the heat method of Marcuse⁹. Sera from two patients with anti-penicillin antibody who had never received cephalothin agglutinated red blood cells coated with penicillin in the indirect Coombs test (cells+serum+ anti-globulin reagent) in titres of 1:256 and 1:1,024. The same two sera, when tested against red blood cells coated with cephalothin, had titres of 1:256 and 1:512, respectively. The two sera directly agglutinated (cells+ serum) group O red blood cells coated with penicillin in titres of 1:64 and 1:128; group O red blood cells coated with cephalothin were directly agglutinated in titres of 1:64 and 1:32, respectively. The direct haemagglutination of red cells coated with penicillin and red cells coated with cephalothin by the anti-penicillin sera was inhibited by prior incubation with penicillin. Inhibition of the indirect Coombs activity required greater amounts of penicillin than were necessary for inhibition of direct agglutination. Cephalothin also inhibited the haemagglutinating activity of these sera against red cells coated with penicillin and red cells coated with cephalothin in both the direct agglutination and the indirect Coombs

Seventy-five blood samples from patients receiving cephalothin were studied. All patients had a history of prior penicillin therapy. Fourteen of these people had agglutinins against cells coated with penicillin and thirteen of the fourteen had positive direct Coombs tests while receiving cephalothin therapy. Forty-one of the seventy-one patients who did not have demonstrable anti-penicillin agglutinins had positive direct Coombs tests while on cephalothin. It was also observed that the positive Coombs tests in the latter group were not as strong as in the former. Twenty eluates were prepared from samples of red blood cells from patients with positive direct Coombs tests while on cephalothin, including six from patients with anti-penicillin agglutinins. Six eluates gave positive results in the indirect Coombs tests against cells coated with cephalothin and all six were from the patients with anti-penicillin agglutinins. Two of these eluates were tested against cells coated with penicillin and gave the expected positive indirect Coombs tests.

These studies demonstrate that sera with anti-penicillin antibody react in vitro with red cells coated with cephalothin and penicillin to almost identical titres. Studies of blood samples from patients receiving cephalothin demonstrate the same type of cross-reactivity. The eluate studies demonstrate the relationships between anti-penicillin antibody, penicillin and cephalothin, and identify the importance of anti-penicillin antibody in the pathogenesis of some of the positive direct Coombs tests in patients receiving cephalothin. The antibody to penicillin seems to bind specifically to cells coated with cephalothin. This represents another mechanism of action other than non-immune, non-specific binding of protein associated with cephalothin on red cells. specific antibody to cephalothin has not been demonstrated.

GENETICS

Pentosuria in a North American Indian

PENTOSURIA, one of Garrod's original four inborn errors of metabolism1, is usually believed to occur almost entirely among people of Jewish descent, whose antecedents can be traced to eastern Europe2. The only well authenticated cases of this disorder to be reported among individuals of other ethnic origin have been in four Lebanese families3,4. We wish to report a case of essential pentosuria in a North American Indian.

During a search for metabolic abnormalities among the patients of a large hospital for mental defectives, simple urinary screening tests disclosed a child whose urine gave a strongly positive reduction of Benedict's solution. When the urine was subjected to unidimensional paper chromatography for sugars in ethyl acetate: pyridine: water (12:5:4), and the chromatograms were developed with a p-anisidine spray reagent⁶, only one sugar was present. This matched authentic xylulose in both its migration rate and its colour. The patient, a severely mentally retarded 10 year old boy, is an Athabascan Indian from a reserve on the British Columbia-Yukon Because there was no evidence that he had border. Caucasian forebears, it seemed important to prove that his urinary sugar was indeed xylulose.

Approximately 500 mg of the sugar was isolated from a specimen of the patient's urine by a modification of the method of Touster et al.7. Urine was passed successively through columns of 'Dowex' 50W-x2, and 'Duolite' A-4. to remove cations and anions, and was then treated with urease to destroy urea. After lyophilization, sugar was extracted from the residue with 95 per cent ethanol. The ethanolic extract was concentrated to a small volume on a rotary evaporator at room temperature, and the concentrate was streaked on to sheets of Whatman 3MMThese were then chromatographed unidimensionally in the ethyl acetate: pyridine: water solvent, and the bands from each chromatogram, shown to contain presumptive xylulose, were cut out, and the sugar eluted from the paper with 95 per cent ethanol. By this technique, small amounts of xylose, which may be produced from xylulose as an artefact on passage through the ion exchange columns, as well as other trace impurities. were removed. Finally, the combined cluates were taken to relative dryness on a rotary evaporator at room temperature, and the resultant thick yellow syrup was further dried over phosphorus pentoxide.

The isolated urinary sugar co-chromatographed precisely on paper with authentic D-xylulose in five different solvent systems. Phenylosazones were prepared from authentic D-xylose and from the isolated urinary sugars. Each had a melting point of 157°-158° C and, when equal portions of the two osazones were mixed, the mixed melting point was elevated to 190° C. In addition, the urine reduced qualitative Benedict's solution within a few minutes at room temperature. These findings support the identifica-

tion of the urinary sugar as xylulose.

The amounts of xylulose present in the urine were quantitated both by paper chromatographic comparison with appropriate standards of xylulose, and by the reduction of quantitative Benedict's solution, as described by Lasker and Enklewitz⁹. Results of both methods were in good agreement, and during two different periods of 24 h the child was found to excrete 7.2 and 4.5 g of xylulose. These figures are higher than the 1.0-4.0 g of xylulosc/day usually excreted by pentosurics2. When the patient was given orally 10 g of p-glucuronolactone, a metabolic precursor of L-xylulose, his rate of urinary excretion of xylulose was tripled for several hours.

Urine specimens were examined from four of the patient's seven siblings, as well as from his mother. None contained xylulose. One sibling, who was found not to have pentosuria, was also mentally defective, and it seems that the patient's mental defect and pentosuria are not causally related.

The presence of essential pentosuria in an Indian from north-west Canada suggests that the gene mutation for pentosuria has occurred more than once in widely diverse human populations, and that the disorder can be expected to be found in other persons who are not of eastern

European or eastern Mediterranean or gin.
We thank Dr O. Touster for a sample of authentic D-xylulose, S. Hansen and D. Love for technical assistance, and Dr B. Tischler, R. Bunting and Sister R. Herle for help with the patient and his relatives. This work was supported by grants from the Medical Research Council and the Department of National Health and Welfare, Canada.

Duplicate Genetic Activities affecting Meiotic Chromosome Pairing at Low Temperatures in Triticum

Common wheat, Triticum aestivum (2n=42), is an allohexaploid with the genomic constitution AABBDD. One of its parents was a tetraploid, like T. dicoccum, with twenty-eight chromosomes and with an AABB genomic constitution. The A, B and D genomes—each of which contains seven chromosomes—were derived from closely related diploid species. Consequently, there are considerable levels of genetic duplication in T. dicoccum and of triplication in T. aestivum. This is formally recognized by the classification of the chromosome complements of both species into seven homoeologous groups2. Homoeologous chromosomes are genetically corresponding members of different genomes the relationships of which are presumed to stem from their evolutionary origin from the same chromosome of the common progenitor of all three diploid ancestors. Twenty-one bivalents are usually formed at meiosis in T. aestivum and there is disomic inheritance. T. dicoccum has a similar diploid-like pattern of chromosome pairing with the regular formation of fourteen bivalents. Several distinct genetic activities are known to affect the regularity of meiotic pairing of T. aestivum³⁻⁵ and it has been inferred that some of these activities are duplicated—being performed at more than one locus^{5,6}. This communication is concerned with the first unequivocal demonstration of such duplication and with the demonstration that different components of the system are responsible for the maintenance of meiotic regularity at low temperatures in different Triticum

Meiotic chromosome pairing is normal in euploid forms of T. aestivum var. 'Chinese Spring' over the temperature range 12°-28° C. There is, however, pronounced pairing failure at 12° C and 15° C in the absence of chromosome 5D,

although pairing is normal at 20° C and 28° C (refs. 5 and 7). Consequently, chromosome 5D performs a genetic activity which stabilizes chromosome pairing against the effects of low temperatures. There is no difference in the extent of meiotic pairing over the temperature range 12°-28° C in AABB tetraploid forms of Triticum, like T. dicoccum⁵. Consequently, because 5D is not present, either some other chromosome must take over the activity performed by 5D in the hexaploid or else normal pairing takes place without this activity at low temperatures in tetraploid To determine the nature of the tetraploidhexaploid difference, T. dicoccum and T. aestivum var. 'Chinese Spring' were compared by experimental breeding.

Hybrids were produced between these species in which chromosome 5D of T. aestivum was either entirely absent or was present in the disomic condition. The 5D-nullisomic hybrids with thirty-four chromosomes resulted from the cross T. aestivum monosomic $5D \times T$. dicoccum; while the 5D-disomic hybrids with thirty-six chromosomes resulted from the cross T. aestivum tetrasomic $5D \times T$. dicoccum. At meiosis, the 5D-nullisomic F_1 plants usually had fourteen bivalents, representing A or B genome pairs, and six univalents, representing the remaining unpaired D genome chromosomes. Meiosis in the 5D-disomic hybrids with thirty-six chromosomes was like that in the 5D-nullisomic hybrids except that there were fifteen instead of fourteen bivalents, the additional bivalent being the 5D pair. These hybrids were allowed to self-pollinate so that F_2 progenies could be obtained. In the 5D-nullisomic F_2 progenies, derived from the hybrids with thirty-four chromosomes, chromosome 5D was never present. By contrast in the 5D-disomic F_2 progenies, derived from the hybrids with thirty-six chromosomes, chromosome 5D was always present in double dose. The F₂ progenies were grown in controlled environment rooms in conditions of continuous light at 15° C. The numbers of chiasmata were recorded in ten pollen mother cells at first metaphase of meiosis in fifty-eight 5D-nullisomic and in eighty-two 5D-disomic plants. Because of the irregular segregation of the six D genome chromosomes which had been unpaired in the F_1 hybrids, the chromosome numbers of these progenies extend from twenty-eight to forty in the 5D-nullisomic F_2 and from thirty to forty-two in the 5D-disomic F_2 . In order to remove differences in chiasma frequencies that simply reflected differences in chromosome number, chiasma frequencies were expressed as mean chiasmata per chromosome for each plant.

In the resulting data there is a striking difference between the progenies with and without chromosome 5D (Table 1). All the 5D-disomic F_2 plants have fifteen or more bivalents and means of more than 0.75 chiasmata per chromosome (Fig. 1). By contrast, in the 5D-nullisomic F_2 there is segregation into two classes in one of which pairing is normal (≥0.75 chiasmata per chromosome) while in the other there is reduced pairing with many univalents and few bivalents (<0.17 chiasmata per chromosome). When F_2 plants which had reduced pairing at 15° C were transferred to temperatures between 20° C and 25° C, meiotic pairing became normal after five days. The ratio of plants in the 5D-nullisomic progeny with normal : reduced synapsis at 15° C is not significantly different from 3:1 $(\chi^2 = 0.0075, P > 0.95)$, but it does not fit a 15:1 or a 9:7 ratio.

From this it can be concluded that, in the 5D-nullisomic F_2 , the disjunct distribution of chiasma frequencies depends upon the segregation of alleles at a single locus. The activity of the dominant allele apparently duplicates

Table 1. Mean chiasmata per chromosome in 5D-nullisomic and 5D-disomic F_a progenies from the cross T. $aestivum \times T$. dicoccum at 15° C (ten cells/plant)

	Mean chiasmata/chromosome		
F_2 type	Reduced pairing (≤0·17 chiasmata)	Normal pairing (≥0.75 chiasmata)	
	(=50-17 cinasmata)	(>0 10 omasmaca)	
5D-nullisomic	14	44	
5D-disomic	0	82	

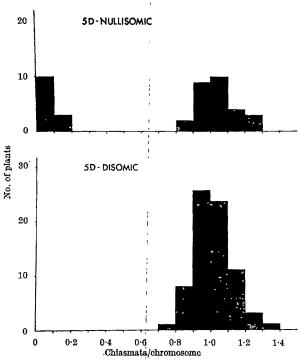

Fig. 1. Histograms showing the distributions of plants over a range of mean chiasmata in each chromosome in F_2 progenies from the cross T. aestivum $\times T$. dicoccum when chromosome 5D was either nullisomic or disomic.

that performed by chromosome 5D of T. aestivum 'Chinese Spring' because its segregation was not revealed phenotypically in the 5D-disomic progeny. It is proposed to call this locus "low temperature pairing" (ltp). The regularity of meiotic pairing at low temperatures in T. dicoccum presumably depends upon the presence of the dominant allele (Ltp Ltp), while T. aestivum 'Chinese Spring' carries the recessive allele (ltp ltp). The chiasma frequencies of F_2 plants in the $5\bar{D}$ -disomic progenies are not strikingly different from those of the high frequency class in 5D-nullisomic progenies. Thus the effects of Ltp and of chromosome 5D are not additive so that the threshold necessary for normal pairing at low temperatures can be attained by a single dose of either Ltp or chromosome 5D. As one activity relates to the long arm of chromosome 5Dit seems likely that Ltp is located on the long arm of a homoeologue. Chromosome 5A of T. aestivum 'Chinese Spring' has been shown to carry out an activity like that of 5D but with much less efficiency. It may therefore be that the alleles by which T. aestivum 'Chinese Spring' and T. dicoccum differ are on chromosome 5A and that l l p is active though less efficient than L t p. The next task is to locate and map Ltp, for when this has been done an assessment will be possible of its relationship with the better known genetic properties of chromosome 5B by which pairing specificity is restricted in *Triticum*.

BIOCHEMISTRY

Isolation of a New Type of Cross Link from the Hinge Ligament Protein of Molluscs

THE two best known elastic proteins are elastin and resilin. So far, elastin has been isolated only from vertebrates although the presence of elastin-like material has been reported in several invertebrates1,2. Resilin has been found only in arthropods3. Apart from their amino-acid composition, resilin and elastin differ in the way they are cross linked into three dimensional networks. Thus resilin contains di- and tri-tyrosine formed oxidatively from tyrosine residues^{4,5} and elastin contains desmosine and isodesmosine⁸ together with a small amount of lysinonorleucine⁷, all formed from lysine residues. The presence in foetal elastin of dityrosine has recently been reported. During an investigation of elastic proteins from other phyla, I noticed that molluscan hinge ligaments contain phenolic compounds, which in several respects resemble dityrosine (Fig. 1). One of these compounds (compound A) has now been isolated and identified as 3,3'-methylene-bistyrosine (Fig. 2). The isolation procodure and the reasons for ascribing the structure in Fig. 2 to the compound are described in this communication; a more detailed description of the properties of the compound will be published later.

> dityrosine 3,3'-methylene-bistyrosine OH OHOHOH CH_2 ĊH2 ĊH2 $\dot{\mathrm{CHNH}}_2$ CHNH, CHNH, CHNH, COOH COOH COOH COOH Fig. 1. Fig. 2.

Whole ligaments of Mytilus edulis were decalcified in 1 molar acetic acid for 48 h and then hydrolysed by refluxing with 6 molar hydrochloric acid for 22 h. The hydrolysate was evaporated to dryness in vacuo over solid sodium hydroxide and thereafter fractionated, as described for hydrolysates of resilin5, on a column of cellulose phosphate (1.6×55 cm). Elution was performed by means of a linear sodium chloride gradient, established by running 1,000 ml. of 1 molar NaCl in 0.2 molar acetic acid into a mixing chamber containing 1,000 ml. 0.2 molar acetic acid. The absorption of the effluent was recorded automatically at 280 mu and fractions of 10 ml. were collected.

One of the major peaks showing absorption in the ultraviolet was located in the region where dityrosine is eluted and this region was taken for further purification. After being evaporated to about 5 ml. it was fractionated on a column of 'Bio-Gel P-2' (1.6 × 55 cm) by elution with 0.2 molar acetic acid. Phenolic compounds are adsorbed to the polyacrylamide matrix of 'Bio-Gel' and are therefore eluted after the inorganic salts, so that the fractionation results both in a purification and a desalting of phenolic compounds. The sample from the ligaments gave two well separated peaks which were eluted after the inorganic salts. The first (compound A) showed maximum absorption in the ultraviolet at 278 mu in acid solution and at 298 mu in alkaline solution; the other compound (compound B) showed maximum absorption at 292 mu in acid solution and at 317 mu in alkaline solution. Both compounds seemed to be homogeneous according to thin-layer chromatography on silica gel with n-butanol-

acetic acid-water (3:1:1 v/v/v) as solvent and according to low voltage paper electrophoresis at pH 2 and 5. At pH 2 both compounds migrate towards the cathode and at pH 5 both appear neutral. They give colour reactions as a-amino-acids and as phenols and they are non-fluorescent. Partial dinitrophenylation according to Silaev et al. showed that both compounds contain two amino groups and because they are neutral at pH 5 it can be assumed that they also contain two carboxylic groups. Spectrophotometric titrations indicated that compound A contains two phenolic groups having pK'-values of 8.0 and 12.5, and that compound B contains two phenolic groups having pK'-values of 7.8 and 11.2. Neither of the compounds will form complexes with boric acid, in contrast to catechol and dityrosine.

Compound A and dityrosine were compared by mass spectrometry. To make them sufficiently volatile the compounds were first trifluoroacetylated and methylated by diazomethane. The results are shown in the first two columns of Table I. Both derivatives are apparently a mixture of the mono- and di-methyl ethers with the monomethyl ether dominant, as the fully methylated derivative of dityrosine has a molecular weight of 608 and the monomethyl ether has a molecular weight of 594. That only one of the phenolic groups is easily methylated must result from the presence of a hydrogen bond between the phenolic Such a hydrogen bond will also explain the unusual acidity found for one of the phenolic groups both in dityrosine⁵ and in compound A. It can also be seen from Table 1 that for each major peak present in the dityrosine spectrum a corresponding peak is present in the spectrum of compound A but located fourteen mass units higher, indicating that compound A might be a methylene derivative of dityrosine. The peaks in the mass spectrum of compound A which have no counterparts in the spectrum of dityrosine can be explained by cleavages occurring between the two aromatic rings. As such a cleavage does not occur in the case of dityrosine and as compound A does not have the biphenolic structure of dityrosine according to the ultraviolet spectra, the most reasonable structure to suggest for compound A will be that of 3,3'-methylene-bistyrosine. This structure is similar to some of the intermediates (novolaks) in the preparation of bakelite from phenols and formaldehyde 10. I therefore attempted to synthesize methylene-bistyrosine by treating 1 mmole of N-acetyltyrosine ethyl ester with 0.5 mmole of formaldehyde in a mixture of 5 ml. methanol and 5 ml. of 2 molar hydrochloric acid. The mixture was refluxed for 5 h and then evaporated to dryness and hydrolysed with 6 molar hydrochloric acid at 110° C for 16 h to remove the blocking groups. The hydrolysate was fractionated on cellulose phosphate in the same way as the ligament hydrolysate. Apart from tyrosine, only one compound was found which emerged in the same position as compound A and which had the same ultraviolet spectrum and the same mass spectrum (Table 1) as compound A, confirming that this compound is identical with 3,3'-methylene-bistyrosine.

The complete structure for compound B has not yet been obtained, but it resembles that of compound A in several respects, such as containing two aliphatic side chains with terminal carboxyl and α-amino groups. This structure makes both compounds well suited as cross links between peptide chains. As the hinge ligament in Mytilus has been reported to be strongly cross-linked11 it can thus be assumed that the function of the compounds is to link the protein chains in the ligament together in a three dimensional network.

The compounds do not only occur in the ligament of Mytilus: both of them are also found present in the inner ligament of Spisula solidissima, and 3,3'-methylenebistyrosine is present in the inner ligament of Pecten maximus. The structure of compound A indicates that it is formed in vivo by linking two tyrosine residues together by means of a one carbon unit. This represents a novel way of forming selerotized proteins which is strikingly different from the formation of both resilin and insect exocuticle.

I thank Professor S. Seifter, Albert Einsten College of Medicine, New York, and Dr D. Williams, University Chemical Laboratory, Cambridge, for their help and

Metabolism of ³H-Myoglobin

PERKOFF¹ has recently emphasized the paucity of information on myoglobin metabolism and the importance of this haemoprotein in the myoglobinurias. Previous attempts to study the turnover of myoglobin by administering ¹⁴C-glycine-2 to rats met with limited success because of the poor incorporation of isotope and non-specific labelling of the molecule (that is, haem and globin). We now describe a new technique for preparing 3H-myoglobin labelled with haem and studies of its turnover and degradation are reported.

Radiochemically pure ³H-Δ-aminolaevulinic acid-3-5 (³H-ALA-3-5), specific activity 400 mc./mmole, was prepared by enolization exchange² and 100 µc. was administered intraperitoneally to hamsters. At intervals, hamsters were decapitated, their musculature was excised and homogenized, and the homogenate was subjected to lead acetate and phosphate precipitation according to the method of Morgan3. The dialysed crude myoglobin which remained in the supernatant was purified by chromatography on DEAE-'Sephadex' (equilibrated and developed with 0.05 molar tris, pH 8.6 (ref. 4)), and on 'Brushite' (developed with phosphate buffers of increasing ionic strength, pH 7.0) columns. The concentration of myoglobin was estimated from the optical density at 420 mu

Table 1. Specific activities of 3H-myoglobin* labelled with habm

Days after injection	Specific activity of haem in myoglobin† (d.p.m./µg)	Specific activity of haem spllt from myoglobin ‡ (d.p.m./µg)	
1	Not done	234	
3	Not done	160	
10	159	157	
19	140	158	
26	154	169	

* Each value represents the average of separate determinations of myoglobin from the muscle of three hamsters injected with *H-ALA-3-5.

† The specific activity of haem in myoglobin is calculated by assuming that the haem content is 3.6 per cent¹⁰. Then d.p.m./µg myoglobin is 0.036 0.036 d.p.m./µg of haem in myoglobin.

of the cyanmet-myoglobin derivative ($E_{1 \text{ cm}}^{1 \text{ \%}} = 53.9$ at 420 mμ according to Cameron⁵ and our own unpublished data). Haem split from myoglobin and crystallized was determined as the pyridine haemochromogen ($E_{mM} = 34.4$ at 557 mu in 25 per cent pyridine?). Counting was performed on 0.5 ml. samples of solution in 15 ml. of Bray's solution⁸ in a Packard liquid scintillation spectrometer.

The ratio of the optical density at 410 to that at 280 m μ of ³H-myoglobin prepared as described was 5.0 (ref. 9) and the material was chromatographed to constant specific activity on DEAE-'Sephadex' and 'Brushite' columns. The specific activity of ³H-myoglobin expressed as d.p.m./ μg of estimated haem in myoglobin (haem = 3.6 per cent of the weight of myoglobin¹⁰) was nearly identical to the specific activity of haem split from 3H-myoglobin (Table 1). In contrast, less than 3 per cent of the radioactivity was present in crude solutions of globin prepared from 3Hmyoglobin. The highest specific activities were obtained in animals killed 24 h after administration of ³H-ALA-3-5 (Table 1). After an initial sharp drop, relatively constant specific activities were observed. Measurable radioactivity persisted in myoglobin obtained from hamsters killed up to 6 months after injection. 3H-Myoglobin was administered intravenously to rats prepared with ligated renal pedicles and cannulated bile ducts. Rats, rather than hamsters, were used for this purpose because of the comparative ease of surgical manipulation. Approximately three-quarters of the administered radioactivity rapidly appeared in bile (Fig. 1), and 80-90 per cent of the radioactivity in bile was identified by crystallization¹¹ as 3H-bilirubin.

These results establish that radiochemically pure, 3Hmyoglobin labelled with haem with specific activities more than 1,000 times greater than those previously achieved with ¹⁴C-glycine-2 can be prepared in vivo in hamsters. They indicate that myoglobin turnover in the hamster is slow and they provide the first direct demonstration that the prosthetic group of myoglobin can be converted to hilirubin.

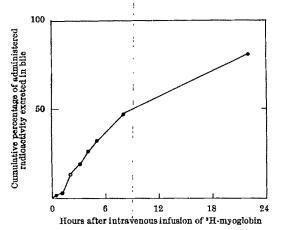

Fig. 1. Excretion of radioactivity in bile after intravenous administration of °H-myoglobin labelled with haem. Data from one representative study are shown. Recipient animals were prepared as described in text.

Effect of Ultraviolet Light on RNA and Protein Synthesis in Differentiated **Epidermal Cells**

STUDIES of the effects of microbeam ultraviolet light on growing tissue culture cells have shown that nucleolar RNA synthesis decreases rapidly but protein synthesis is either not affected1 or is decreased as a result of inhibition of nuclear RNA synthesis2. The influence of ultraviolet light energy on formation of macromolecules in more differentiated cells, however, has not been adequately studied. In the present study we examined the effects of heterochromatic ultraviolet light on RNA and protein synthesis in granular cells of human epidermis in vivo. These cells are differentiated epidermal cells which do not replicate, but do actively synthesize RNA and protein.

Three sites of the upper arm in eighteen volunteers were exposed to a mild erythemal dose of ultraviolet light from a hot quartz, high-pressure Hanovia contact lamp $(5\cdot1\times10^6 \text{ to } 10\cdot2\times10^6 \text{ ergs/cm}^2)$. Ten μ c. of ^3H -cytidine (specific activity $3\cdot6$ c./mmole), ^3H -histidine (specific activity 4 c./mmole) and 3H-leucine (specific activity 5 c./mmole) diluted in 0.1 ml. of sodium chloride solution was injected intradermally in separate sites at 1, 3, 6, 24, 48 and 72 h after ultraviolet irradiation. Non-irradiated control sites were injected with these substances in a similar manner. Biopsies were secured at 15 min after injection of 3H-cytidine and at 30 min after injection of the amino-acids. Tissues were prepared for autoradiography using NTB-2 emulsion and 3 weeks' exposure time, followed by haematoxylin and eosin staining.

In non-irradiated sites we observed incorporation of ³H-cytidine and ³H-histidine in almost all cells in the basal and spinous layers, but, in the granular layer, 17.7 per cent of cells did not label with 3H-cytidine and 10.4 per cent did not label with 3H-histidine: these results are to be published. Epidermal cells seem to synthesize RNA and protein continuously as they move towards the surface from the basal layer to the spinous and granular layers. Some granular cells, however, stop the synthetic process at one of the terminal differentiation stages just before they become horny cells. After irradiation the number of granular cells synthesizing RNA and protein decreased rapidly as shown in Fig. I. Within 1 h 80·1 per cent and 47.1 per cent of granular cells were not labelled after injection of 3H-cytidine and 3H-histidine, respectively. Percentage of unlabelled granular cells increased to 94 per cent and 83.1 per cent at 3 h after irradiation, and by 6 and 24 h almost all granular cells did not label with injected 3H-cytidine and 3H-histidine. Morphologically, these granular cells did not show any significant changes during the first 24 h after radiation, whereas some cells in the Malpighian layer became degenerative with pyknotic nuclei and densely eosinophilic and homogenized cytoplasm by 6 h. Synthesis of RNA and protein was markedly inhibited in the degenerated Malpighian cells, but basal cells appeared morphologically unchanged and continued to synthesize RNA and protein.

These observations were confirmed by comparing grain counts in the granular layer and basal layer of the epidermis after injection of ³H-histidine and ³H-leucine. A Whipple eyepiece micrometer disk was placed at the border between the epidermis and dermis for determination of the number of grains in the basal layer, and at the upper edge of granular cells for examination of grain counts in the granular layer. Because the number of grains actually appearing in the section varied considerably from one individual to another, ratio of counts obtained in 200 squares in both layers was computed, taking the count in the basal layer as one. In nonirradiated epidermis the concentration of grains in the granular layer was four times greater after injection of ³H-histidine and 1.5 times greater after injection of ³Hleucine as compared with that of the basal layer. After irradiation the ratio of grain counts was reversed, being higher in the basal layer (Figs. 2 and 3). This indicated that protein synthesis in granular cells was markedly inhibited.

Biochemical studies have indicated that ultraviolet light immediately inhibits RNA and protein synthesis in the skin3. Morphological changes in the skin, however, have not been reported to occur before 12-24 h after irradiation4.5. In the present study it was possible to correlate the early biochemical changes in epidermal cells with their morphology by means of autoradiography. The results demonstrated that ultraviolet light energy inhibited both RNA and protein synthesis in granular cells which are highly differentiated long before the structural changes reported to date. Reduction of incorporation of amino-acids was observed within 1 h. It takes more than 1 h for newly synthesized RNA to move from the nucleus to the cytoplasm, and so the decrease in protein synthesis observed in granular cells seems to be a result of a direct effect of ultraviolet light on cytoplasmic protein synthesis rather than of decrease in RNA synthesis. Cellular degeneration and RNA and protein syn-

thesis inhibition were noted in Malpighian cells by 6 h after irradiation. In contrast, basal cells appeared morphologically unchanged and continued synthesis of RNA and protein.

Haptoglobin acting as a Natural Inhibitor of Cathepsin B Activity

Observations in this laboratory on various homogenates and on tumour ascites fluid1,2 have suggested that a component in blood plasma acts as a powerful cathepsin In order to study this interesting finding, cathepsins B and D were first separated by gel filtration from the lysosomal pellet of calf liver homogenates and subsequently studied in their partially purified form. For the colorimetric assays edestin denatured with urea was used as a substrate in 0·1 molar acetate buffer at pH 5.0 according to Ottoson and Sylvén¹. Both 0.004 molar cysteine and 0.05 EDTA must be added for maximum cathepsin B activity. Without their addition, or with added cysteine alone, extinction increments which were too small and erratic were obtained. By means of this system the cathepsin B and D activity changes could then be studied separately after the addition of small amounts of all the different available purified plasma protein fractions from normal human blood. One fraction only prepared from Cohn's fraction IV-b containing the haptoglobins exhibited a marked inhibitory effect on the cathepsin B activity. This inhibition was noted even at weak haptoglobin concentrations amounting to a quarter of the amount of enzyme. No inhibition was found on addition of other highly purified serum proteins such as transferrin, ceruloplasmin or $\alpha_{\text{\tiny I}}\text{-acid}$ glycoprotein, nor by addition of pure sialic acid, which is a component of haptoglobin. The cathepsin D activity, however, remained totally uninfluenced by all of the plasma fractions.

Through the courtesy of the KABI Co., a sample of higher purity (human haptoglobin RFE 76) was supplied containing more than 90 per cent haptoglobin. preparation showed a much stronger inhibition at the same concentrations as the first fraction (Fig. 1). inhibition was reversible. When a certain amount of enzyme and haptoglobin were mixed and a dilution curve of the activity of this sample was determined, a non-linear curve was obtained showing a downward curvature suggesting the presence of a dissociable inhibitor-enzyme complex. Preincubation of haptoglobin and cathepsin B for different lengths of time did not abolish the effect. Further analyses were made using various substrate and haptoglobin concentrations; evaluation in a Lineweaver-Burk diagram³ showed that the kinetics of the enzyme reaction behaved as expected for a non-competitive type of inhibition. A study of the pH-dependence showed

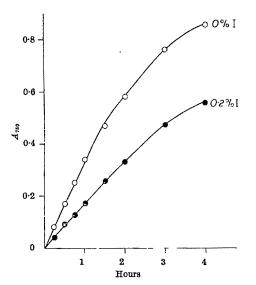

Fig. 1. Hydrolysis of urea-denaturated edestin by purified cathepsin B at pII 5·0. Each sample of 50 μ l. contained 600 μ g edestin, 20 μ g cathepsin B. I=0, no haptoglobin added; I=0·2, 20 μ g haptoglobin added; cysteine+EDTA present.

further that the inhibition occurred over the whole pHrange of enzyme activity. In addition to the protein substrate edestin, haemoglobin denatured with urea was also investigated and the same result was obtained. When the artificial substrate BANA (N-benzoyl-DL-arginine- β -naphthylamide) was used, however, according to Goldbarg and Rutenburg⁴, no enzyme inhibition was found. This may be because of the hydrophobic character of BANA.

Experiments were further designed to separate a mixture of haptoglobin and cathepsin B on a 'Sephadex G-200' column. The two components could be separated and the original activity of cathepsin B was regained. In the separation diagram, however, the curve of cathepsin B seemed distorted when compared with a diagram where cathepsin B alone had been filtrated. This is to be expected when the small molecule of cathepsin B is dragged along with the much larger haptoglobin molecule before they dissociate.

Trypsin was investigated in the same way, but no inhibition was found when haptoglobin was added. There is thus a considerable difference in behaviour between cathepsin B and trypsin toward haptoglobin. enzymes split peptide chains at the same amino acids. Trypsin splits the haptoglobin molecule easily, but cathepsin B cannot hydrolyse haptoglobin. It seems that the inhibitor is reversibly bound to cathepsin B in a manner which alters the enzyme structure so that its active group cannot work.

It seems, from the literature, to be very difficult to obtain a haptoglobin free from contaminations of other proteins. The haptoglobin we used carries less than 10 per cent of contaminating substances. Results so far obtained strongly suggest that haptoglobin or one of its major components (?) is the cathepsin inhibitor. Because part of the cathepsin B activity extends above pH 7 the presence of a physiological plasma inhibitor would seem of importance for the protection against active proteolysis. It is also noticeable that conditions such as inflammatory processes, tumour diseases and major tissue injury where cathepsin B will be liberated are associated with increased amounts of haptoglobin in the blood plasma6.

We thank Dr R. Ottoson and Dr B. Sandberg of the Research Department of the KABI Group, Inc., Stock-

holm, for the supply of purified serum protein fractions.

Improved Multi-enzyme Analyser

By a relatively simple adaptation of the Technicon autoanalyser system, it was possible to develop a technique for the automatic assay of groups of enzymes1. reaction mixture—for example, a tissue homogenate, buffer and any co-factors common to all the enzymes in the group—flows continuously through the analyser. Different substrates are then introduced through the automatic sampler, so that the various enzymes in the homogenate which react with these substrates are assayed in sequence.

This system, in a relatively simple form, has been used to study oxidases, phosphatases, NAD-linked dehydrogenases and a variety of ferricyanide reductases1-3. Experience with these simpler systems, however, revealed two important difficulties. In the first place, it was difficult to obtain a suitable concentration of enzyme mixture (for example, the tissue homogenate) which gave optimum rates for all the enzymes in the group. This was because the enzymes were not present in equal amounts in the mixture, and the least active enzymes required protein concentrations in the assay which were far too high for the most active enzymes. Second, the simpler multiple enzyme analysis system previously used only provided a single time of incubation for each assay, as is the case for the majority of Technicon enzyme assay systems. As a result, it was impossible to establish whether the enzymes had been assayed in conditions in which the rate of reaction was linear with respect to time.

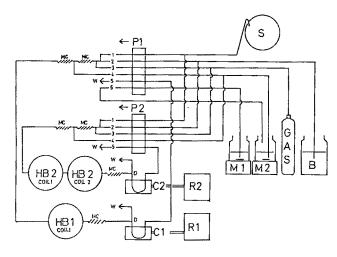

Fig. 1. Manifold for multi-enzyme analyser. B, Buffer plus any cofactors common to all enzymes in group; C1, C2, continuous flow colorimeters; D, debubblers; HB1, HB2, variable temperature heating baths; M1, M2, magnetic stirrers; MC, mixing coils; P1, P2, proportioning pumps; R1, R2, recorders; S, sampler table, containing substrates; W, waste. Channel 1 consists of P1, HB1, C1 and R1 and channel 2 of P2, HB2, C2 and R2. Stock enzyme is placed in mixer 1 and pumped through line 6 of pump 1 into mixer 2, which contains a suitable diluent. The diluted "enzyme gradient" is pumped out of mixer 2 by line 4 in each pump. Time of incubation in each channel depends on flow rates of lines (see Table 1).

By incorporating a simple gradient-making device into the system, the assays have now been performed with a continuously increasing protein concentration in the reaction mixture. Thus the relationship between reaction rate and protein concentration is obtained automatically. Moreover, a double analytical system is now used, so that two incubation times are provided for each assay. In this way it is possible to check that the reaction is linear with respect to time. The principles of the method are illustrated by experiments with ferricyanide reductases of yeast.

The analytical system is shown in Fig. 1. It consists essentially of two channels. Channel 1 contains a proportioning pump, P1, a heating bath with one time delay coil, HB1, and a colorimeter, C1, connected to a recorder, R1. The second channel is identical (P2, HB2, C2 and R2) except that the heating bath contains two time delay coils. Substrates are placed in cups in the automatic sampler, S, and the stream of substrates is split and fed into both channels. Similarly, buffer and any common co-factors are placed in the vessel B and fed into both channels. The substrate and buffer streams are segmented by a suitable gas which is fed into both channels from a common cylinder. The enzyme mixture is placed in a mixing flask, stirred by a magnetic stirrer, M1. The flask is

kept at 0° C either by a temperature jacket connected to circulating ice-bath, or more conveniently by standing i in ice in a container of low thermal conductivity, such a an 'Igloo' container. The enzyme solution is then intro duced into a similar vessel on a second mixer, M2, by means of line 6 in the first pump. The second vessel con tains a suitable volume of diluent, and as the concentrated enzyme solution drips into it, the diluted solution is pumper out into the two channels by line 4 in each pump. The shape of the "enzyme gradient" can be altered by using lines of different flow rates, and depends on the relative rates of filling and emptying of vessel M24. If line 6 in pump 1 has the same volume as line 4 in pumps 1 and 2 the rate of emptying is exactly twice the rate of filling and a linear gradient results. The slope of the gradient is determined by the rates of filling and emptying, and by the volume of fluid originally present in the vessel M2 Provided that enough solution is present for the assay, the volume of fluid in vessel M1 need not be determined accurately.

If the substrates are placed in repeating groups in the sampler table, it is possible to obtain a series of readings at different protein concentrations for each enzyme. As an example, the assay of a group of four dehydrogenases in yeast will be described. These are NADH dehydrogenase, L (+) lactate dehydrogenase, D (-) lactate dehydrogenase and succinate dehydrogenase. All the enzymes are followed by measuring the reduction of potassium ferricyanide at 4200 Å, in phosphate buffer pH 7.4 and with a low concentration of neutral detergent ('Triton X-100') which serves to reduce the turbidity of the suspensions, activate any latent enzymes and also improve the bubble pattern in the autoanalyser. Using sampler type I there are places for forty cups on the sampler table, and they are filled as follows. All even numbered cups contain water, in order to provide efficient washing between samples. (If the improved sampler II is used, this is not necessary.) The substrates, and water to provide blanks, are arranged as follows: (a) water in cups 1, 11, 21 and 31; (b) NADH in cups 3, 13, 23 and 33; (c) sodium L (+) lactate in cups 5, 15, 25 and 35; (d) sodium D (-) lactate in cups 7, 17, 27 and 37; and finally (e) sodium succinate in cups 9, 19, 29 and 39. In this way, there is a water blank between each group of assays, and the most active enzymes are assayed first, in the first group. The composition of the buffer and the enzyme source are given in Table I, together with the flow rates of the lines in the manifold. The results of a typical assay are given in Fig. 2, and for clarity only the

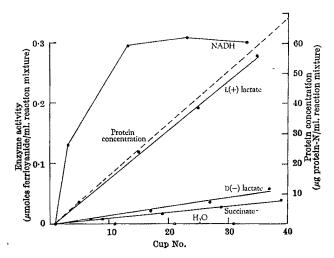

Fig. 2. Results of multiple enzyme analysis of ferricyanide reductases. Manifold is given in Fig. 1 and details of assay conditions in Table 1. Protein concentration (---) was calculated from protein concentration in the stock enzyme suspension, and from a calibration curve obtained by pumping mmolar potassium ferricyanide through the gradient-making system (see ref. 2). Results given for channel 1 only, with 7-3 min of incubation.

Table 1. ASSAY CONDITIONS FOR MULTIPLE ENZYME ANALYSIS OF FOUR DEHYDROGENASES

Channel	Line	Description of lines Description of line	Flow rate			
No.	No.		(ml./min)			
1	1	Sample	0.60			
	2	Buffer	2.00			
	3	Gas	1.20

	5	Waste	2.50			
	6	Enzyme (from mixer 1)	1.20			
2	1	Sample	0·60			
	2	Buffer	2·00			
	3	Gas	1·20			
	4	Enzyme (from mixer 2)	1·20			
	5	Waste	2·50			
Reaction mixture						
Line Buffer Buffer Buffer Sample Sample Sample Sample Gas	10 mmolar sodium L $(+)$ lactate (cups 5, 15, 25 and 35)					

Gradient started with 100 ml. of 0·3 molar mannitol in mixer 2 and 100 ml. of yeast homogenate (strain D243) containing 0·28 mg protein-N/ml. in 100 ml. of 0·30 molar mannitol. Bath temperature 37°, sampler rate 40/h with water in even-numbered cups and cups 1, 11, 21 and 31. Measurements at 4200 Å. Times of incubation were 7·3 mln for channel 1 and 11·6 min for channel 2.

values for the first channel, with 7.3 min of incubation, are given.

It can be seen from Fig. 2 that the method automatically reveals the assay conditions in which enzyme activity is linear with respect to protein concentration. Thus the values for NAD-ferrievanide reductase are far from linear, and a most reliable estimate of the specific activity would be obtained from the readings at the beginning of the enzyme gradient. The other enzymes, however, give reasonably linear curves. Also the least active enzyme, succinate dehydrogenase, is scarcely measurable at the beginning of the gradient, but a more reliable value can be obtained at the highest protein concentration. The initial slope of the curves in Fig. 2 gives the best estimate of the enzyme activity in each unit of enzyme protein. The values in Fig. 2, however, are only obtained from a single incubation time. If the initial slopes of the similar family of curves obtained from channel 2 are calculated, it is possible to plot the reaction against time, as shown in Fig. 3. It can be seen that all the activities calculated in this way seem to have been reasonably linear with respect to time.

The method of expressing the results in Figs. 2 and 3 is convenient for comparing the relative activities of the

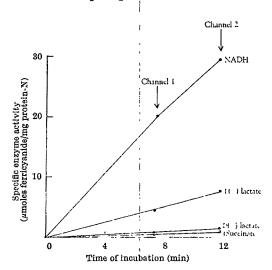

Fig. 3. Progress curve from dual channel analyser. The initial slopes of the plots of enzyme activity against protein concentration (Fig. 2) were calculated for the four enzymes, using results from both channels. Value in channel 2 for NADH-ferricyanide reductase is 8 per cent below value for linearity.

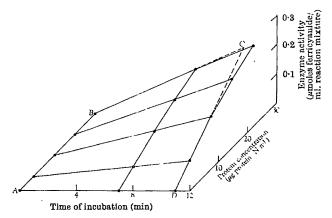

Fig. 4. Three dimensional plot relating incubation time, protein concentration and enzyme activity. Results with D(-) lactate ferricyanide reductase. Assay conditions as in Table 1, except that a respiratory deficient yeast (strain 45 $ac \times 188 up$) was used (see ref. 3). Stock enzyme suspension in mixer 1 had a concentration of 0·12 mg protein-N/ml. Surface ABCD represents an ideal assay in which the enzyme activity is both linear with respect to time, and proportional to protein concentration.

enzymes in the group. It is also of interest, however, to combine all the measurements made with an individual enzyme in one three dimensional diagram, in which the enzyme activity is plotted along the X axis, time along the Y axis and protein concentration along the Z axis. Examples of such plots from two other experiments are given in Figs. 4 and 5. These diagrams reveal the assay conditions under which the enzyme activity is both proportional to protein concentration and linear with respect to time. Conditions of perfect linearity are given by the surface ABCD in Fig. 4, and deviations from these conditions can readily be seen in the three dimensional diagrams.

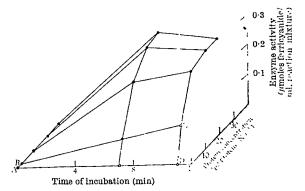

Fig. 5. Three dimensional plot with severe deviation from linearity. Results with NADH ferricyanide reductase. Assay conditions as in Table 1 except that yeast strain 40×41 was used. The stock enzyme suspension had a concentration of 0-15 mg protein-N/ml. Note that results are only linear in the surface ABCD.

By combining a dual channel system with the use of a gradient of protein concentration (see refs. 5, 6 for similar systems for single enzymes), the multi-enzyme analyser described here can thus provide results of precision and validity comparable with manual assays based on progress curves carried out over a range of protein concentrations. Clearly, by combining suitable gradient mixing devices with the flexibility of the Technicon system, it would be relatively easy to develop systems for the automatic study of such parameters as K_m , K_i , pH optima, heats of activation and thermal stability not only with individual enzymes, but also with groups of enzymes which have some common feature in their assay. There is no limit to the complexity of analytical systems which can be set up with modern automated equipment for studying enzyme catalysed reactions, and this system is a compromise between such complexity and ease of operation.

I thank Miss J. Jones for technical assistance and Dr D. Wilkie for supplying strains of yeast. I am also grateful to the Medical Research Council and the Science Research Council for financial aid.

Phosphate Esters of Human Erythrocytes: Synthesis of ITP-14C from Inosine-8-14C

THE recent finding of relatively large concentrations of inosine triphosphate (ITP) ($44-51~\mu g$ of phosphorus/g of haemoglobin) in erythrocytes obtained from two members of a family led to a closer investigation of the nucleotide composition of normal erythrocytes. A detailed analysis of several samples of fresh human erythrocytes revealed the presence of small amounts of ITP in an average concentration of 1.8 µg of phosphorus/g of haemoglobin². From these studies it was concluded that ITP is a normal constituent of human erythrocytes.

High voltage paper electrophoretic separation of phosphate om fresh erythrocyte haemolysates obtained from four different subjects, and treated with **P-orthophosphate.

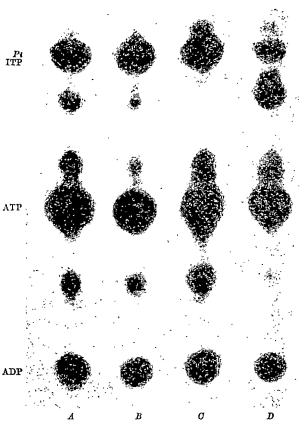

Fig. 2. High voltage paper electrophoretic separation of phosphate esters from inosine incubated blood obtained from the same subjects illustrated in Fig. 1. Following incubation, the washed crythrocytes were haemolysed and treated with *2P-orthophosphate.

While preparing sedoheptulose-1,7-diphosphate labelled with phosphorus-32, by incubation of whole blood with inosine and labelled orthophosphate2,3, analysis of the S-1,7-P "zone", obtained by high voltage paper electrophoretic separation of acid-soluble phosphate esters labelled with phosphorus-32, disclosed in a few samples the presence of labelled ITP in concentrations significantly higher than 1.8 μg phosphorus/g haemoglobin, the average concentration of ITP in normal fresh erythrocytes. The increase in concentration of ITP (up to 3-9 µg phosphorus/g haemoglobin) found in the conditions of the experiment suggested that in a few cases the erythrocyte can synthesize ITP in vitro from added inosine. Moreover, it points out the difference between samples of blood in their ability to synthesize ITP from inosine.

The rapid isotope equilibrium exchange between 32Porthophosphate, ATP and added nucleoside triphosphate carried out by haemolysates in the cold4 can be used as a qualitative test for detecting ITP in erythrocytes. For this purpose red cells obtained from fresh blood or blood previously incubated with inosine and phosphorus were haemolysed with a solution of 32P-orthophosphate. mixture was allowed to stand for 0.5-1 h, and the acidsoluble phosphate esters obtained4 were then separated by high-voltage paper electrophoresis3.

The electrophoretic patterns of 32P-labelled phosphate esters of fresh erythrocytes and erythrocytes from inosine incubated blood, respectively, are shown in Figs. 1 and 2. Fig. 1, sample D, shows an additional phosphorus-32 spot corresponding to ITP. This sample was obtained from the blood of one of the two siblings found to contain high ITP concentrations. Fig. 2 shows the same blood samples as in Fig. 1 after incubation with inosine and treatment with 32 P-orthophosphate. In samples A and B 32 P-ITP spots of

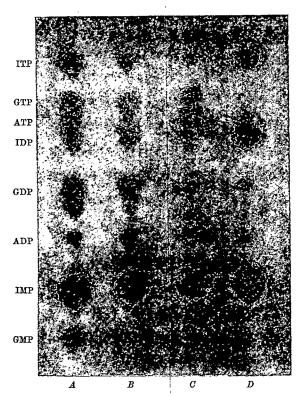

Fig. 3. High voltage paper electrophoretic separation of phosphate esters from inosine-8-¹⁰ incubated blood obtained from the same subjects illustrated in Figs. 1 and 2. This particular sheet was exposed for 6 months to facilitate photographic reproduction.

different intensities appeared; in contrast, sample C shows no detectable ITP spot.

To confirm the in vitro synthesis of ITP from inosine, experiments were carried out with inosine-8-14C. The high voltage paper electrograms of the acid-soluble phosphate esters were exposed to 'No-screen' medical X-ray film for 3-6 weeks. In these circumstances distinct spots corresponding to radioactive Hx, Is, IMP, ITP (and occasionally IDP) are seen. In addition, several other minor spots can be recognized which migrate at rates similar to those of the guanosine and adenosine mono-, di- and tri-phosphates, respectively. Their identity was confirmed by paper chromatography in three different solvent systems⁵. As seen in Fig. 3, inosine-8-¹⁴C was incorporated in ITP (and IDP), in addition to IMP, the extent of incorporation depending presumably on the ability of the particular erythrocytes to synthesize ITP from inosine. The ratio of counts ITP/IMP falls essentially into three groups: 0.14-0.21 for the erythrocytes with high ITP concentration; 0.01-0.1 for erythrocytes which can synthesize ITP; and 0.001-0.003 for erythrocytes with low concentration of ITP, and which do not show increase in concentration of this nucleotide on incubation with inosine.

There is no evidence in the literature for the formation of ITP from inosine in human erythrocytes. The studies of Lowy et al.⁸ with inosine-8; ¹⁴C show that most of the labelled compound is found in the form of IMP with a fraction of the counts in GTP and ATP. Analogous results were obtained by Bishop' when studying the degree to which hypoxanthine is incorporated into the acid-soluble nucleotides of whole human blood. Kleins, working with an active haemolysate preparation from human erythrocyte, found that adding hypoxanthine to the system gave rise only to IMP. Similar results were reported by Mager et al.9. That ITP was not detected by these workers in their particular systems may be because there is a low percentage of individuals with erythrocytes capable of synthesizing ITP, and that ITP itself is present in erythrocytes in relatively low concentrations. The biosynthesis of ITP and the possible genetic link between high ITP erythrocytes and ITP synthesizing erythrocytes is under investigation.

Phylogeny of the Neurohypophysial Hormones

VERTEBRATE neurohypophysial hormones have a common structural pattern characterized by a chain of nine aminoacid residues with a disulphide bridge connecting the amino-acids in positions 1 and 6. There are usually two hormones in each species, the active principles rarely varying from one species to another within a given class. Thus oxytocin and arginine vasopressin have been chemically identified in five species of mammals belonging to the orders Primates, Artiodactyla, Perissodactyla and Isotocin (Ser₄-Ile₈-oxytocin) and vasotocin (Args-oxytocin) have up to now been isolated from six species of bony fish belonging to the families Gadidae, Scombridae and Cyprinidae. The structural variations which occur between one vertebrate class and another are confined to one or two amino-acid substitutions in positions 3, 4 or 8 (for a review of this subject see ref. 1).

There seems to be a particular neurohypophysial hormone heterogeneity in the cartilaginous fish, although the existing evidence for the three principal groups, the rays, sharks and Holocephali, is contradictory. It was originally thought that there was only one hormone in several elasmobranchs². Nevertheless, two active principles were shown to be present by exchange ion chromatography in two species of ray, Raia clavata3 and Raia batis4, in one shark, Squalus acanthias3,5, and in one of the Holocephali, Hydrolagus collei⁵. It now seems probable that the cartilaginous fish, like most of the vertebrates, have at least two hormones. These two principles, however, are present in most unequal proportions: vasotocin, which according to the pharmacological data seems to be one of these factors, is present in only a very small amount, in contrast with the relatively high amount found in the bony fish. The hormone present in greatest quantity, glumitocin (Ser₄-Gln₈-oxytocin), was identified in the rays and isolated from the hypophyses of Raia clavata3 and Raia batis4, while its presence in Raia naevus and Raia fullonica has been identified during current research.

216 mg of pituitary acetone powder has been prepared from sixty-eight Raia naevus hypophyses and 125 mg from fourteen glands of Raia fullonica. The respective titres for the oxytocic activity, determined by the Holton method with a physiological solution without magnesium, were 10 mm U.S.P./mg and 3.5 mm U.S.P./mg; 100 mg of material was extracted twice with 8 ml. of 0.01 normal sulphuric acid at 4° C for 24 h, the insoluble residue was removed, the extract concentrated to about

4 ml. and the pH adjusted to 3.9. Ten mg of beef neurophysin was added and three consecutive precipitations of the neurophysin-hormone complex made with sodium chloride at 15 per cent (18 h), 10 per cent (4 h) and 6.5 per cent (18 h), each precipitate being dialysed and redissolved in 4 ml. of 0.5 molar acetate buffer, pH 3.9 (refs. 8 and 9). The final precipitate was dialysed, redissolved in 4 ml. of 0.25 per cent acetic acid and the complex was dissociated with 5 per cent trichloroacetic acid which precipitated the neurophysin but left the active principles in solution in the supernatant. This solution was de-acidified by passing it through a column of 'Amberlite IR 45' $(1 \times 6 \text{ cm})$ and it was then freeze-dried. The hormones were separated and purified by paper chromatoelectrophoresis. Electrophoresis was carried out in a pyridine acetate buffer, pH 3.7, for 2 h at 60 V/cm, followed by chromatography in an n-butanol-acetic acid-water (4:1: 5 v/v/v) system for 18 h. Development with dilute ninhydrin (0.01 per cent in alcohol) usually detects only one peptide, but a more sensitive pharmacological method was used which consisted of cutting the sheet into 3 cm pieces, eluting with 1 per cent acetic acid and determining the oxytocic, pressor is and hydro-osmotic activities. By this method the presence of two hormones was found in each species of ray.

Table 1. AMINO-ACID COMPOSITION OF RAY GLUMITOCIN

Amino- acid	Raia clavata molar ratio using Asp as reference	Raia naevus molar ratio using Asp as reference	Raia fullonica molar ratio using Glu as reference	Number of residues per mole
Asp	1.00	1.00	0.76	1
Ser	0.84	1.07	0.84	1
Glu	1.12	1.17	1.00	1
Pro	0.95	0.76	0.76	1
Gly	1.34	1.19	1.00	1
Tle	0.95	0.89	0.83	1
Tyr*	0.58	0.53	0.30	1
Cvs*	1.52	0.86	1.22	2

*Tyrosine and cystine undergo partial destruction when the peptide is hydrolysed after elution on paper. Cystine was determined in a separate sample after oxidation to cysteic acid with performic acid. The preparations contain small quantities (less than 0·2 residue) of Ala, Thr and Leu.

A first principle was demonstrated with chromatographic and electrophoretic migrations similar to those of vasotocin and also with oxytocic, pressor and hydro-osmotic activities. Its chromatographic migration compared with alanine as reference was 0.50-0.60. The amount present was too small to determine the amino-acid composition of this hormone. With alanine as reference, the second principle had a migration of 0.85-Only its oxytocic activity was appreciable. When determined in the presence of magnesium' the oxytocic activity was seen to be increased some ten times. After hydrolysing with 6 normal hydrochloric acid in vacuo in a sealed tube at 105° C for 48 h, the product was analysed for amino-acids in a Spinco 120 \bar{B} automatic analyser12. The amino-acid composition resembled that of glumitocin isolated from Raia clavata³ and Raia batis⁴ (Table 1). The quantities used for analysis were of the order of 0.02-0.05 μmole which corresponded approximately with 0.15-0.50 units of oxytocic activity. A study of the structure of the peptide isolated from Raia clavata showed that it was Ser₄-Gln₈-oxytocin². The products obtained from the other three species took up the same position during chromatoelectrophoresis (electrophoresis at pH 3.7 in a pyridine acetate buffer; chromatography in n-butanol-acetic acid-water solvent) and had the same amino-acid composition. It could be concluded from this that glumitocin was present in all four species of ray and that the ray group shows a certain uniformity in this respect. According to Perks and Sawyer¹³, however, Raia ocellata has a hormone which is pharmacologically distinct from those found in the other species of ray.

We thank Miss Du Buit and the Marine Biological Laboratory of the Collège de France (Concarneau), who kindly furnished the Raia naevus and Raia fullonica glands. This investigation was supported in part by a grant from the Délégation à la Recherche Scientifique et Technique.

Pink Spot, p-Tyramine and Schizophrenia

Boulton et al.1, using monodimensional paper chromatography, confirmed the presence of the pink spot in urines of some schizophrenic and Parkinsonian patients and claimed that it was not caused by 3,4-dimethoxy-βphenylethylamine (DMPEA) but by p-tyramine. It has been suggested2 that the much discussed pink spot may have been caused by p-tyramine and, furthermore, that this compound may be causally related to schizophrenia or Parkinson's disease. With regard to these suggestions, it might be pertinent to consider some of our findings which were obtained with urines from normal subjects and from chronic schizophrenic patients.

Using a bidimensional thin-layer chromatographic technique³ (sec-butanol: formic acid (100 per cent): water in proportions 40:1:6 and isopropanol: ammonia (15 normal): water in proportions 8:1:1), we routinely distinguished the spot caused by p-tyramine from that tentatively identified as DMPEA. Both DMPEA and p-tyramine produced a pink spot when treated with ninhydrin followed by Ehrlich's reagent. Co-chromatographic techniques confirmed the presence of p-tyramine

in all control and schizophrenic subjects tested.

Our thin-layer technique did not allow a precise quantitation, and so a number of 24 h urine samples were assayed for p-tyramine by a fluorometric procedure. No significant difference was found in the excretion of p-tyramine between chronic schizophrenics and normal subjects (Table 1). The amounts of p-tyramine excreted varied considerably, in both schizophrenic and control subjects. Determinations of both p-tyramine and nitrogen in 24 h urine collections from twenty-three schizophrenic subjects showed a fair correlation (r = 0.62, P < 0.005) between the two (Fig. 1), indicating that tyramine excretion is, at least in part, a function of the amount of protein ingested. This relationship is supported further by the observation that patients fed glucose (no protein) have a markedly diminished excretion of tyramine. In consideration of

Table 1. URINARY EXCRETION OF p-TYRAMINE IN CHRONIC SCHIZOPHRENICS AND NORMAL SUBJECTS

	No. of subjects	No. of samples	$\mu \mathrm{g}/24~\mathrm{h}$	Range
Schizophrenics Controls	28 12	37 24	496 ± 27* 593 ± 55	(210–908) (247–1,240)

* Average ± S.E.

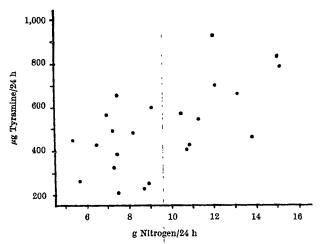

Fig. 1. p-Tyramine and nitrogen excretion in 24 h urine samples from twenty-three schizophrenic subjects.

these observations on p-tyramine excretion, it would be difficult to attribute significance to the finding by Boulton et al.1 of what they call an abnormally high concentration of p-tyramine in the urine of one schizophrenic subject. In any case, our results do not support the hypothesis of a relationship between schizophrenia and urinary excretion of p-tyramine.

The amount of p-tyramine found by Boulton et al. in their sample from a schizophrenic patient is approximately 30-200 fold greater than the amounts of DMPEA reported by other investigators3,4,6-11 to be present in the urine of schizophrenics and healthy controls. p-Tyramine is a normal urinary constituent found in all individuals by paper chromatographic as well as by fluorometric methods^{5,12,13} and so its absence in a large percentage of schizophrenics (fifty-six out of sixty-seven) and in some Parkinsonian patients (four out of twenty) as reported by Boulton et al. 14.16 does not agree with the incidence of p-tyramine excretion described here and by other investigators.

This investigation was supported by the Illinois Mental Health Fund and a US Public Health Service research grant from the National Institute of Arthritis and Metabolic Diseases.

Instability of Amitriptyline Base

AMITRIPTYLINE hydrochloride is an antidepressant which produces mild tranquillizing side effects (Fig. 1a). During an investigation into a death caused by the ingestion of amitriptyline it was noticed that the free base, a colourless oil prepared from a tablet for reference purposes, became yellow on standing. Thin-layer chromatography (silica gol G.F.; methanol: acetone 1:1 v/v) showed that the yellow material travelled further than the free base and unlike the base showed no colour reaction with potassium iodoplatinate. Gas liquid chromatography of the fresh base showed a single peak. On standing for 2 days, a second peak appeared, presumably corresponding to the yellow breakdown product. Some of this yellow compound was separated by thin-layer chromatography and analysed by infrared spectrophotometry. Comparison between the spectrum of the impurity and that of the pure base suggested that the aliphatic double bond had been oxidized to yield a ketonic product. The strong aliphatic-N-(CH₃)₂ stretching frequencies at 2,760 and 2,800 cm⁻¹ were absent and there was an increase in the relative intensities of aromatic over aliphatic bands.

Approximately 1 g of amitriptyline hydrochloride was then oxidized with 5 per cent potassium permanganate. The resulting solution was extracted with chloroform and a dark yellow oil was obtained from the solvent. On elution from a silica gel column with ethyl acetate, a yellow band moved quickly through the column and was Evaporation of the ethyl acetate yielded a collected. yellow oil which seemed to be on the point of crystallizing, but attempts to produce crystals from various solvents failed. The infrared spectrum of this oil between potassium bromide plates was identical with that previously obtained and both spectra were shown to be consistent with the Sadtler Index spectrum of 5H dibenzo (a,d) cycloheptene 5-one 10,11 dihydro (Fig. 1b). The nuclear magnetic resonance spectrum of this yellow oil in deuterochloroform measured against tetra methyl silane was also consistent with this structure (Fig. 2)four benzyl protons (3.1 p.p.m.) and eight aromatic protons (7.2 and 7.8 p.p.m.).

Although we have so far failed to detect 5H di-benzo (a,d) cycloheptene 5-one 10,11 dihydro in the urine of patients taking amitriptyline, the presence of a substantial amount of a neutral metabolite is indicated and work is being continued to identify this compound. Because of the rapid deterioration of the free base, a knowledge of this

BIOLOGY

Water Economy of the Ostrich

STUDIES of the physiology and water relations of desert birds have dealt with a few carinate species1, but practically nothing is yet known of the adaptations of the ostrich Struthio camelus L. to hot, dry environments. Because it is large, the ostrich cannot obtain shelter from the rigours of its environment in the manner of smaller birds, but we have found it to possess salt-excretory nasal glands which enable it to utilize saline water. At least one subspecies, S. camelus massaicus, frequents the neighbourhood of salt and soda lakes2. It has been suggested that ostriches can exist on dry or succulent food without needing free water, but no experiments have previously been carried out to confirm this. therefore investigating the water economy of S. camelus in the Sudan.

Results obtained so far show clearly that the ostrich must have access to drinking water, even in winter when the temperature in the shade varies between about 10° and 30°C with a relative humidity of 10-30 per cent. In these conditions, half-grown ostriches (about 13 kg) lost weight steadily when deprived of water, although they were given either dry food (millet) or green vegetables. They easily withstood a loss of 25 per cent of their body weight which was reached after 9 days of dehydration (the lethal point was evidently about 34 per cent). A maximum of 2.4 l. of fresh water could then be ingested at one time by the birds, which represents about 96 per cent of the total loss in body weight during the period of dehydration. During dehydration, the daily intake of food was reduced from an average of 300 g to about 170 g of millet; the water content of the faeces was reduced by 22.4 per cent and the body temperature tended to rise. Cloacal temperatures ranged between 37.7° and 40.0° C in control birds and between 38.8° and 41.0° C in dehydrated birds.

When fresh water was not available, ostriches drank dilute sea water and solutions of sodium chloride. They maintained their weight on 20 per cent sea water or 0.2 molar sodium chloride solutions, but lost weight steadily when given higher concentrations. In the Sudan, ostriches live in desert and semi-arid regions where some water or succulent foods are available. In the summer, they migrate to places where succulent food is abundant, even when water is not available in the immediate neighbourhood.

These observations indicate that ostriches can survive dehydration to a greater extent than can gazelles3 and more closely resemble the camel in this respect².

Respiration in Polyzoa (Ectoprocta)

THE accepted view that zooids of the Polyzoa (or Ectoprocta) are small enough for gaseous exchange to be achieved by diffusion has recently been challenged. Mangum and Schopf¹, having measured oxygen consumption in Bugula turrita, concluded that diffusion alone was insufficient to supply oxygen to all parts of the zooid. They proposed a circulation of body fluid, brought about by the periodically repeated process of retraction and protrusion of the lophophore and tentacles, which is observed in these organisms. This, they supposed, would cause the transfer of oxygen-rich coelomic fluid from the region of the lophophore and tentacle sheath to the lower part of the zooid.

Mangum and Schopf's calculations can be criticized on biological grounds. First, they assume mixing of the lophophoral fluid with that of the main coelom: this is unlikely. The coelomic lumen of each tentacle opens into a ring coelom surrounding the mouth, these components together making up the lophophoral coelom or mesocoel. The only connexion between the mesocoel and the metacoel is through a transversely elongated pore beside, and nearly closed by, the nerve ganglion^{2,3}. While some movement of fluid between mesocoel and metacoel is obviously possible, the morphological arrangements do not suggest that this could be other than on a very small scale.

Second, acceptance of their figures for oxygen consumption invokes the unlikely premise that the internal viscera have the same kind of oxygen demand as the ciliated cells of the tentacles, which are beating continuously to create feeding currents. Such arguments do not disprove their hypothesis, but they render it less attractive.

Finally, however, Massaro and Fat4 have re-examined the data by applying standard mathematical techniques to the analysis of a diffusion system containing a chemical reaction. They found that the oxygen consumption of the polypide could be completely accounted for by diffusion alone.

Neither of the recent contributions on this subject1,4 has, however, considered the position in other Polyzoa. Whereas Bugula zooids can be considered as semi-cylinders with a flat surface which is membranous and readily permits gaseous exchange, the zooids of many other Polyzoa have all their walls calcified and display certain adaptations which seem to facilitate gaseous exchange by diffusion.

In the Cyclostomata, the zooid consists of a long cylindrical tube, the distal opening of which is closed by a membrane. Protrusion of the tentacles is achieved in a different manner from the Cheilostomata, to which Bugula belongs. The fact that the tentacle sheath does not protrude beyond the orifice of the zooid, as it does in the Cheilostomata, will largely preclude its functioning as an organ of respiration, while the less pronounced movements of the polypide, plus the presence of an annular septum in the metacoel, make extensive mixing of the coelomic fluid unlikely. (For a full description of the zooid and the method of protruding the tentacles, Borg's paper should be consulted.)

The body wall in cyclostomes comprises an epidermis (lined by a peritoneum), calcareous layer and cuticle. The skeletal calcareous layer is perforated by "pseudopores", filled with living tissue. It has been supposed^{2,3} that these permit gaseous diffusion through an otherwise impermeable wall. Borg³ even noted the paucity of pseudopores in the vicinity of the terminal membrane, which must be sufficiently permeable to gases to render the pores superfluous. The gonozooid, which contains large numbers of developing embryos, bears about twice as many pseudopores per unit area of surface as the normal zooid. It seems clear that this must be to satisfy the high oxygen requirements of the embryos, which can obviously be met only by diffusion, because here there is no polypide to promote circulation.

A recurring evolutionary trend in the Cheilostomata is the protection or elimination of the frontal membrane found in Bugula and other genera classified as Anasca. In the Ascophora, the front wall of the zooid is calcified and the hydrostatic function of the frontal membrane is performed by the ascus, a thin-walled sac opening directly to the exterior, into which water can flow as a decrease in coelomic volume forces out the tentacles (for diagrams, see ref. 6). In addition to its role as a compensation sac, the ascus may be the principal respiratory organ in asco-The rhythmic movements withdrawing and protruding the tentacles will keep emptying the ascus and refilling it with fresh, oxygenated water.

The frontal wall of ascophorans also often contains pseudopores. They may permit gaseous exchange to some extent, but this is probably not their primary func-Unlike cyclostomes, most ascophorans deposit secondary calcification on the outside of the initial skeletal layer. How this is achieved, remotely from the epidermis, has never been satisfactorily explained, but the tissues in the pseudopores are clearly involved. Thus, when the pseudopores are restricted to the margin of the zooid, secondary calcification spreads from the margin centripetally (producing a pleurocyst); when they cover the primary wall, secondary calcification takes place all over the surface (producing a tremocyst) (for diagrams

It is concluded that anascans and non-calcified Polyzoa have no diffusion problem; in cyclostomes it is met by pseudopores, varying in frequency of occurrence, which permit diffusion of oxygen from outside. In the ascophorans, pseudopores are again present, but often only at the margin of the zooid, and they seem to fulfil a different function; the ascus is perfectly adapted as an efficient respiratory organ, and the behaviour of the organism seems to ensure that it does so.

Diurnal Activity of Hermatypic Gorgonians

THE natural food of gorgonians, or any other soft corals, inhabiting coral reefs is unknown, but net photosynthesis to respiration ratios from 2 to 5 have been reported for isolated colonies of five species of Caribbean reef gorgonians in laboratory experiments^{1,2}. This photosynthesis is attributed to the dinoflagellate symbionts living in the

Table 1. NUMBER OF GORGONIAN COLONIES WITH EXPANDED OR CONTRACTED POLYPS IN DIFFERENT CONDITIONS OF LIGHT

Cloudy day (ncon ±1 h) Bright sun Twilight (noon ±1 h) (7 p.m. ±1 h) Night (9-10 p.m.) Polyps expanded Polyps contracted 166 (81) 39 (19) 100 (44) 129 (56) 427 (85) 73 (15) 85 (57) 63 (43)

Numbers in parentheses are percentages of all colonies observed in the specified condition.

gastrodermal cells of these and other so-called hermatypic corals. There is also evidence that members of the gorgonian family Xeniidae in the Red Sea draw most of their nutrition from this photosynthesis3. Observations reported here suggest that gorgonians from Caribbean reefs may also depend for nutrition on their algal symbionts.

Equipped with self-contained underwater breathing apparatus and with a hand-tally in either hand, I observed every gorgonian I could find in six patches of corals on reefs less than 7 m deep off the upper Florida Keys during 3 weeks in June 1966. I made these observations in full sunlight, in complete overcast, in twilight and at night. I counted gorgonian colonies whose polyps were expanded on one tally and colonies whose polyps were contracted on the other. The few colonies which were partially expanded were not counted.

Table 1 shows the pooled results of these observations. The polyps of these hermatypic gorgonians on these reefs tend to be expanded during the day and contracted at night. No attempt was made to make such counts for individual species, but my impression was that the sea fans, Gorgonia, seldom varied from this condition, while the abundant members of the genus Pseudopterogorgia seldom showed this trend but tended to be expanded at night and contracted in the daytime.

In the same conditions of light, I collected plankton over the reefs with a 20 mesh/cm net of 25 cm diameter towed within 1 m of the sea surface from a skiff travelling at 1-3 knots. None of the tows lasting 20 min in daylight caught more than twenty or thirty organisms, but the net became clogged and the 50 ml. collecting jar overflowed with plankton within 5 min during every night

Close-up moving pictures of several gorgonian species taken on the reef in bright sunlight and at night by artificial light show (a) the trend of gorgonian polyps other than those of Pseudopterogorgia to be expanded in the daytime and contracted at night and (b) the paucity of visible plankton in daytime and its abundance at night. Stony corals such as Montastrea cavernosa and Diploria clivosa seem to be mostly contracted in daytime, but at night they are expanded and actively catching and ingesting swarming zooplankton.

The fact that the polyps of most gorgonian species I have observed expand in the daytime when zooplankton is scarce and when conditions are right for photosynthesis leads me to suggest that many of these species on shoal Caribbean reefs may draw most of their nutrition from the photosynthesis of their algal symbionts. The predominantly contracted state of these polyps at night when zooplankton is abundant suggests that these gorgonians do not feed extensively on zooplankton.

Overwintering in Pemphigus bursarius (L.)

Алтноиси many aphids overwinter in the egg stage, several species can overwinter in the adult stage as parthenogenetic morphs (Aphis pseudobrassicae Davis1, some Dysaphis Börner spp.², Aphis gosypii Glover³, Pemphigus betae Doane⁴, etc.). The physiological mechanisms involved in overwintering by the parthenogenetic morphs of aphids have not been widely studied. I have used Pemphigus bursarius L., which can overwinter as adult virginoparae even in the absence of the host plant⁵, to show that overwintering adults are physiologically distinct from virginoparae living on lettuce roots during the summer.

'Webb's Wonderful' lettuce seedlings, germinated in a modified Hoagland's nutrient solution, were transferred to plastic pill boxes lined with damp filter paper. Some of these cages were placed in a room supplied with artificial light giving a long photoperiod (17 h light and 7 h dark) and kept at about 18° C, and others were placed in cabinets equipped with lights to give the same photoperiod and kept at a temperature of 10° C. Single virgino-parous adults of *P. bursarius* from a laboratory culture initiated by winged emigrants from poplar galls collected in Harpenden, Hertfordshire, were introduced to cages at both temperatures and were allowed to produce three to six offspring. The adults were then removed. At 18° C. offspring became adult virginoparae after 13-14 days. (Some offspring became sexuparae at this temperature; these results will be discussed elsewhere.) The adults started to reproduce the same day, or the day after the adult moult. Offspring born at 10° C took about 20 days to become adult but did not reproduce, although they were kept for up to 56 days after the adult moult at this temperature.

Adults reared at 10° C were retained at that temperature for varying periods, then removed to fresh seedlings and kept at 18° C. Reproduction did not commence immediately after removal to the higher temperature. The length of delay before the onset of reproduction in adults reared in the cold was about 3 weeks for aphids retained at 10° C for 4–9 days after the final moult and 2 weeks for those retained in this way for 33 days.

Adults reared at 18° C and 10° C were fixed in alcoholic Bouin after the final moult, embedded in 'Ester Wax 1960' and sectioned at 7μ (Figs. 1 and 2). The overall size of these adults was similar but there were marked anatomical differences. In adults reared at 18° C, the embryos were larger at a later stage of development and more numerous than the embryos of adults reared at 10° C. The fat body was, however, more extensive in adults reared at 10° C than in those reared at 18° C.

Fig. 1. Longitudinal section of adult virginopara of *P. bursarius* reared from birth at 10° C showing extensive fat body (F) and retardation in development of embryos (M).

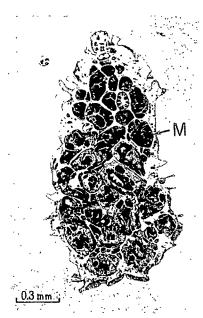

Fig. 2. Longitudinal section of adult virginopara of $P.\ bursarius$ reared at 18° C with numerous well developed embryos.

The failure of adult virginoparae, reared at 10° C, to reproduce without delay when transferred to 18° C, the failure of embryos to develop and hypertrophy of the fat body, all suggest that these adults were in a state of reproductive diapause. Whether adult virginoparae of P. bursarius reared at 10° C are considered to be in a state of reproductive diapause or quiescence, they are physiologically distinct from summer virginoparae and as such are separate morphs, termed hiemalis. The hiemalis are adapted for survival rather than reproduction, as the large food reserves (fat bodies) show. The few small embryos may be associated with a low rate of respiration. It is possible that the occurrence of such morphs, specially adapted for overwintering, is widespread among other species of the Aphididae which have facultative or obligatory anholocycles.

The economic importance of overwintering colonies of aphids is still to be investigated. It seems, however, that these colonies could build up more rapidly in the spring on host plants of commercial importance and cause damage earlier in the season than colonies initiated by winged emigrants from winter host plants.

Phototactic Response of Euglena gracilis to Polarized Light

Phototaxis (translational movement in response to a light stimulus) in the single cell micro-organism *Euglena gracilis* can be used as a means for studying sensory perception at the molecular level. This process seems to be controlled by a primitive visual system consisting of a

photoreceptor, at the base of the flagellum, and a pigmented shading device called an eyespot¹⁻³. Euglena rotates about its long axis as it swims, and thus in the presence of light from one side the photoreceptor will be periodically shaded by the eyespot. It has been suggested that this shading causes a succession of phobic responses (shock reactions) which act to point the organism towards the light source. Once the organism is properly oriented, a continuous shading of the photoreceptor results and no further phobic response occurs. (It is possible that the inverse is true, that is, that the shock response occurs on shading the photoreceptor. There is, however, some evidence against this type of mechanism, for example, negative phototaxis in eyespotless Euglena and the polarized light effect described in the present work.)

Evidence has been presented which indicates that Euglena has a greater motility in linearly polarized light than in ordinary light. Furthermore, many species of animals, mostly arthropods such as the crab Cardisoma, are capable of detecting the orientation of the plane of polarization of light, and germinating spores of the fungus Botrytis and the fern Osmunda orient their growth relative to the polarization plane of a light stimulus. Thus we felt it would be of interest to determine whether polarized light has an effect on the phototactic response in

Euglena.

Euglena gracilis, strain Z, was grown as in our earlier work⁶ using a lactic acid medium described by Wolken². White light (maximum intensity about 140 ergs cm⁻² sec⁻¹) from a 500 W tungsten projection lamp was used in all experiments^{6,7}. Heat was removed using watercooled infrared absorbing glass. Polarized light was obtained by placing a sheet of 'Polaroid' in the stimulating beam. Phototaxis was measured using a "phototaxigraph" designed in this laboratory. Basically, this instrument is a chopped double beam turbidimeter which uses near infrared light in the measuring and reference beams and which photoelectrically records the accumulation of organisms within a lighted region. A diagram of the optical configuration of the phototaxigraph is shown in Fig. 1. All other experimental details were as previously described^{6,7}.

In Fig. 2, "phototaxigrams" showing the effect of plane polarized light on phototactic accumulation are given. When the plane of polarization of the stimulating light (a collimated beam about 2 mm wide) was oriented so that its electric vector was perpendicular to the long axis of the sample tube (a cylindrical cuvette approximately 10 cm in length), a normal phototaxigram was obtained (Fig.

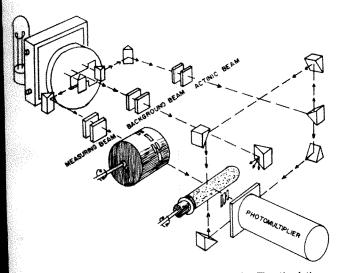

Fig. 1. Optical configuration of the phototaxigraph. The stimulating (actinic) light is incident on the sample cuvette from above and below. The measuring beam passes through the same region of the cuvette but at right angles to the actinic beam.

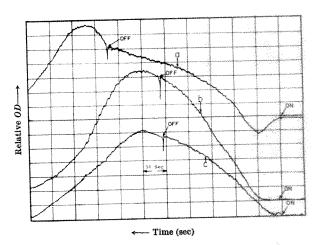

Fig. 2. Comparison of phototaxigrams obtained using polarized stimulating light and unpolarized stimulating light. a, Polarized light with E-vector parallel to the long axis (axis of rotation) of the tube; b, unpolarized light; c, polarized light with E-vector perpendicular to thong axis (axis of rotation) of the tube. Curves represent optical density at approximately 8000 Å in the illuminated zone (ordinate) against time (abscissa; sequence of events from right to left). Optical density proportional to number of organisms. Downward spike when light is turned off is merely a marking device.

2b, c). The lower rate and extent of phototaxis in curve 2c, as compared with curve 2b, is the result of the lower intensity of stimulating light.

Rotating the plane of polarization so that the electric vector was parallel to the long axis of the sample tube produced a distinctly different phototactic behaviour of the Euglena (Fig. 2a). Intermediate positions of the polarizer produced phototaxigrams of intermediate shape. The characteristic features of the polarized light effect (curve 2a) are an initial negative phototaxis occurring immediately on turning the light on, and a sudden influx of Euglena into the illuminated zone when the light is turned off.

In the absence of any orientation of individual Euglena with respect to the sample tube, a mechanistic explanation for different phototactic responses to different orientations of plane polarized light is difficult to envisage. We therefore looked for such orientation in our experimental system. In the phototaxigraph, the sample tube is rotated at 10 r.p.m. about its long axis so as to keep the Euglena from settling and to expose all sides of the tube to the same amount of light'. Photomicrographs of Euglena suspensions in the rotating and non-rotating tube were taken and are shown in Fig. 3. It can be seen that when the tube is not rotating the organisms are randomly oriented, but when the tube is rotating the organisms are mostly aligned perpendicular to the axis of rotation, probably in response to the flow of medium. consistent with the observation that free-swimming protozoa orient themselves against a current*.

This finding not only allows an interpretation of the phototactic behaviour but also gives information about the molecular geometry of the eyespot. If we assume that the pigment molecules in the eyespot* are ordered with respect to the plane of the organism, then the initial negative phototaxis can be interpreted as a shock reaction produced when actinic light which is polarized so as not to be absorbed by the eyespot pigments (that is, so that the plane of polarization is perpendicular to the molecular electronic transition moment) illuminates the photoreceptor. This shock reaction is experienced by those Euglena directly in the stimulating beam and causes a decrease in the number of organisms within the illuminated zone, probably by causing a reversal of swimming direction

^{*} It is difficult to formulate an explanation of our results, particularly the switch from positive to negative phototaxis as the plane of polarization of the stimulating light is rotated, based on an ordering of pigment molecules in the photoreceptor and not in the eyespot.

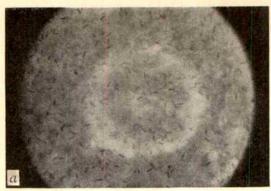

Fig. 3. Photomicrographs of Euglena gracilis in a non-rotating (a) and a rotating (b) tube $(\times 60)$. Axis of rotation of tube is coincident with its long axis, which is oriented vertically within the plane of the paper.

at the dark-light interface. This type of response would be analogous to the negative phototaxis observed with eyespotless mutants9, which is probably the result of direct stimulation of the photoreceptor.

Those Euglena outside the illuminated zone are exposed to scattered light, which will have lost much of its polarization. Thus, as shown in Fig. 2a, after an initial period of negative phototaxis caused by the shock reaction, a positive slope corresponding to positive phototaxis is observed.

There is usually a 15 sec lag time after the unpolarized light is turned off, caused chiefly by inertia in the swimming motion of the Euglena, during which the organisms will continue to accumulate within the previously illuminated zone9. With polarized light, as in Fig. 2a, the rate and extent of such accumulation are much greater than with unpolarized light. This is probably produced by a combination of the normal inertial lag and a cessation of the opposing shock reaction to polarized light.

A specific statement concerning the geometry of the pigment molecules within the eyespot can be made by a consideration of the fact that only light polarized with its plane parallel to the axis of rotation of the sample tube, and thus perpendicular to the long axis of the aligned Euglena, produces the negative shock reaction. If our interpretation of the negative response is correct, the pigment molecules must be aligned in the eyespot so that their molecular transition moments are parallel to the long axis of the organism. The pigment molecules in the eyespot are known to be carotenoids3. The molecular transition moment associated with the long wavelength absorption band of carotenoids is parallel to the plane of the extended conjugated double bonds. The carotenoids, in the eyespot of Euglena, must therefore be arranged with the long axes of the molecules parallel to the long axis of the organism. (This interpretation implies that the pigment molecules in the photoreceptor are either not oriented, are oriented differently from those in the eyespot (if they are

carotenoids), or are not carotenoids and have differently polarized transitions.)

The ordering of pigment molecules in the phototactic organelle is reminiscent of similar situations in the arthropod eye4, in the mammalian retina10 and in the chloroplast11. One wonders whether this is an accidental result of the necessity of having a high pigment concentration in a shading device, such as the eyespot, or whether the ordering has physiological significance in providing Euglena with a mechanism for orienting with respect to the plane of the polarized light in its environ-

Soluble Carbohydrates in the Seeds of Tropical Pasture Species

TAXONOMISTS have used the composition of the soluble carbohydrate fraction of grass seeds in the biochemical differentiation of grass species1,2. Sucrose is usually the most abundant sugar, but the presence of the raffinose group in the seeds of certain ten perate species of grasses and legumes has been established. McLeod² found raffinose and stachyose in the seeds of Brachypodium spp. whereas Bromus spp. contained neither, and of twenty two temperate species of Gramineae examined she found raffinose in 70 per cent and stachyose in 45 per cent.

We have examined the seeds, extracted in 80 per cent ethanol, of the tropical grass species Cenchrus ciliaris (Buffel), Chloris gayana (Rhodes) and Setaria sphacelata and the tropical legume species Stylosanthes humilis (Townsville lucerne), Glycine javanica and Phaseolus atropurpureus c.v. siratro, by paper chromatography in ethyl acetate-pyridine-water (10:4:3) with 3-4 per cent p-anisidine hydrochloride in butan-1-ol-ethanol-water (4:1:1) as spray reagent. Raffinose and stachyose were present in the seeds of all three legume species but were absent from the grass species (Fig. 1a and b).

In all the tropical grass and legume species examined, fructan (identified by alcohol-resorcinol test and isolation) was found in the deproteinized, cold-water extracts of the seeds previously extracted with ethanol. It seems therefore that de Cugnac's classification of the Gramineae into levulifers and sacchifers based on the presence or absence of fructan cannot be applied to the seeds of tropical species.

We suggest that the presence or absence of the raffinose roup in the seed may provide a means of distinguishing etween tropical grass and legume species.

APPLIED SCIENCE

Effects of Particle Size Range in the Differential Thermal Analysis of **Powders**

ALTHOUGH the technique of differential thermal analysis s widely used in the study of materials in powdered form, here seems to be considerable uncertainty as to whether he particle size characteristics of the material influence he thermograms obtained. The general consensus of

opinion would seem to be that the mean particle size might have some effect; the possible effect of the spread of particle size in the sample appears, however, scarcely to have been considered.

In connexion with research in which we are engaged, it is necessary to study the peaks arising from the transformation of extremely small quantities of material and, in consequence, it is essential that due allowance should be made for the effects of any differences arising from the particle size characteristics of the different samples. In order to investigate this question, forty-seven tests have been carried out on samples of quartz sand, from a single source; the samples being prepared, from the natural sand, by sieving between sieves of known aperture.

The size distribution of the samples is defined in terms of two parameters

 $M = \frac{d_2 + d_1}{2}$

and

$$D \, = \, \frac{2(d_2 - d_1)}{(d_2 + d_1)}$$

where d_1 and d_2 are the apertures, in μ , of the finer and coarser sieves, respectively. Thus M is the mean particle size of the sample, and D is the spread of the sample. the latter being expressed in terms of the mean particle size of the sample.

The element of the thermogram which has been studied is the peak corresponding to the α/β transformation of quartz. The area of the peak is defined in the way shown in Fig. 1; the base of the peak area being obtained by the projection of the line CD before the peak. This procedure is justified because an independent analysis shows that the slope of this portion of the thermogram is independent of the particle size characteristics of the samples of quartz used.

The equipment used was a 'Standata 625' apparatus (Stanton Instrument Co.), fitted with a 'Sintox' block head. The weight of the samples used was 285 mg ± 1 mg and the samples were lightly tamped with a stainless steel rod.

The test results have been analysed on the basis of a double linear regression and the following relationship obtained.

$$A = 0.160 + 2.4 \times 10^{-6}M - 1.4 \times 10^{-2}D$$

where A is the area of the peak in square inches. statistical analysis of the data then reveals that, at the 95 per cent confidence level, there is: (a) no significant correlation between the area of the peak and the mean particle size of the material $(0.02 < M \le 2 \text{ mm})$; and (b) a significant correlation between the area of the peak and the spread of the particle size of the sample (0.2 < D < 2).

The present conclusions definitely relate only to the α/β transformation of quartz and to tests carried out with a particular apparatus. Thus, possibly, they are inapplicable to peaks relating to other types of transformation, and to tests made with apparatus of different design.

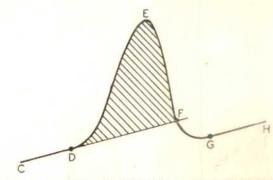

Fig. 1. Construction used for defining the area of the peak of the thermo-

In view of the paucity of information relating to this question, however, this communication is published in order to draw attention to errors which could arise when the results of tests carried out on samples of different particle size range are compared.

GENERAL

Diatomaceous Earth: Scanning Electron Microscope of 'Chromosorb P'

DIATOMACEOUS earth, as mined in Lompoc, California, and other sites in the south-west United States, is made up of the siliceous skeletons of diatoms which lived in the Miocene and Pliocene periods. The mined diatomite is crushed, blended, pressed into brick and fired at 900° C for use as high temperature insulation. When ground, this material, known as 'Chromosorb P' (Johns-Manville Corp.), is sold as a support for the liquid used in the gas chromatographic separation of organic compounds. Some of the diatom skeletons were found to be intact after this rigorous treatment. It has been estimated that as many as 10,000 species of diatoms may be found.

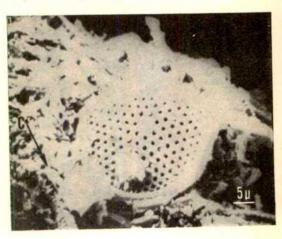

Individual diatoms and composites have been examined by optical and electron microscopy to try to obtain a better understanding of their function in the gas chromatographic column. Optical techniques lack depth of focus, so at best, only a small depth of material can be observed. The electron microscope provides additional resolution, but, because it is also a transmission instrument, it shows the composite of the whole specimen. The 'Stereoscan' scanning electron microscope provides a means of observing the surface of the specimen with considerable depth of focus, even at high magnification.

Many diverse samples can be examined with this instrument—for example, transistor terminals³ and soil micro-organisms⁴, and we are currently examining pollen and meteorite surfaces. An investigation of the solid support used in gas chromatography was suggested because questions have been raised about the physical features of the modified diatomite relative to the size of the pores and the size of the openings through which the gas would flow.

Previously, investigators have had to rely on indirect observations to establish the type of pores (mercury-intrusion method) and the surface area (Brunauer-Emmett-Teller, gas adsorption method). Early studies⁵, in which the pore size distribution was measured with and without varying quantities of stationary phase, concluded that the pore size distribution was between 0.4 and 2μ for 'Chromosorb P'. Verification by direct observation was desired to estimate the distribution and types of holes in 'Chromosorb P'.

Part of the surface of a particle of 'Chromosorb P' is shown in Fig. 1. The view shown in Fig. 1(a) shows the variety and complexity of the particle surface. The part

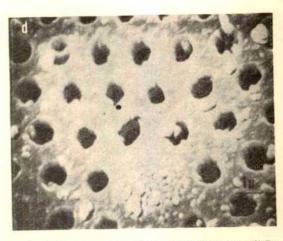

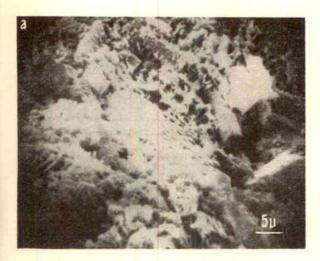

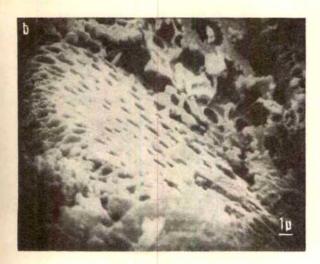

Fig. 1. Surface of 'Chromosorb P'. (a) Surface and diatom skeletons; arrow A. Coscinodiscus; arrow B. side view of a similar diatom; (b) Coscinodiscus, and arrow C. Plagiogramma; (c) and (d) enlarged views of Coscinodiscus.

of Fig. 1(a) indicated by arrow A is shown further in Figs. 1(b), (c) and (d). Similar diatom skeletons are seen throughout the area, either in valve view or at some angle to the surface. It can be seen that many of these are broken and the edges are clearly in view. These diatoms are believed to be of the genus Concinodiscus.

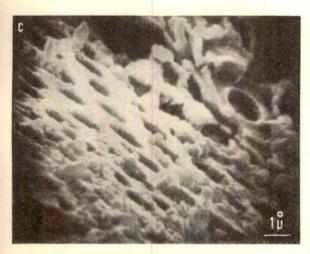

Fig. 2. Side view of the surface of Coscinodiscus.

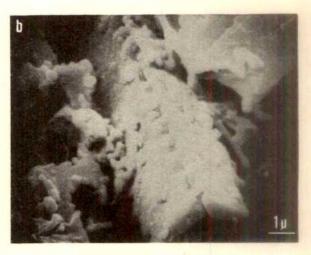

Fig. 3. Fragment of Plagiogramma.

The particle indicated by arrow B of Fig. 1(a) is shown in Fig. 2. Fig. 2(a) provides further information on the fragments surrounding the more complete skeleton. Figs. 2(b) and (c) show the height of the particles on the surface, hole dimensions and spacing. The surface particles are seen to be 0.2 to 0.5 μ in diameter and are up to 1 μ high,

The spacing between holes (primary structure) in the surface of the diatom skeleton in both Figs. 1 and 2 is about 0·7 to 1·1μ. These uniformly spaced holes are about 0·5 to 0·8μ in diameter. The immediate area around each hole appears to be slightly raised. The total diameter of the specimen is approximately 23 μ.

A second diatom skeleton is indicated by arrow C in Fig. 1(b). This is believed to be of an unidentified according genus. Such forms make up a small part of the population of diatoms in the particle. An enlarged view of this specimen is shown in Figs. 3(a) and (b). Although there is some slight roughness of the surface, the surface features of this skeleton are much less prominent than that of the Coscinodiscus of Figs. 1 and 2. The outstanding features of this specimen are the valve-like longitudinal protuberances. Fragments of other species are readily evident in Fig. 3(a) also.

Another area of the particle, showing many additional surfaces, can be seen in Fig. 4. Of particular interest is the girdle view of the broken diatom, believed to be similar to the *Coscinodiscus* of Fig. 1. This is of particular interest to workers in gas chromatography, for it relates to the spreading of the liquid phase. Figs. 4(a) and (b)

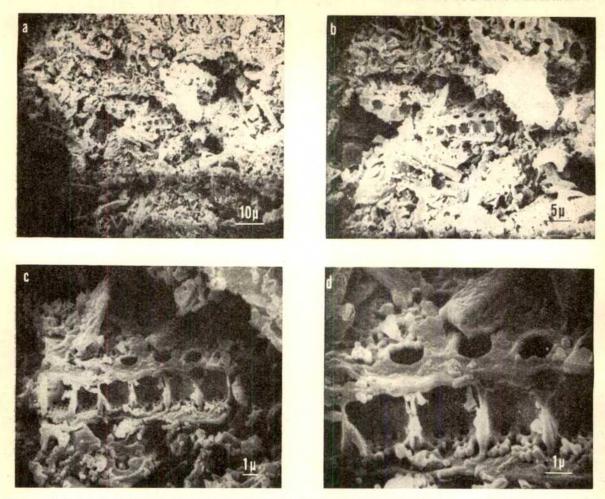

Fig. 4. Surface of a particle of 'Chromosorb P'; (a) and (b) 'Chromosorb P' fragments including area of (c) and (d) side view of diatom Coscinodiscus.

show the large number of these fragments which are present in some parts of the 'Chromosorb' particle and the inter-relationship of the broken diatom skeletons in the particle as a whole. Figs. 4(c) and (d) present a more detailed view of the surfaces which are similar to that of Figs. 1 and 2. These protuberances and the finely divided fragments probably account for the high surface area measured by Baker et al.5. The holes in this specimen are found to be similar to those of Figs. 1 and 2. The dimensions of similar shaped diatom skeletons reported by Ottenstein as viewed in thin-section were found to vary between 50 and 20µ. This lower value is in general agreement with our observations and may be peculiar to the particular species examined. The electron micrograph of Ottenstein, where the primary hole structure has dimensions of approximately 3µ, is also probably a different species because 0.5-0.8 u openings are observed in Figs. 1, 2 and 4. Furthermore, considerable variation in size from form to form may be found in any given species.

The holes in the lower portion of the Coscinodiscus were found to vary from 0·1μ to more than 0·4μ and are similar to the secondary structures indicated by Ottenstein which were approximately 0.5µ in diameter. The chambers seen in Figs. 4(c) and (d) are 1.5 to 2.0 u in diameter and 1.5μ in height, and have an estimated volume of 1.5 × 10-8 μl. Because such a small quantity of liquid would be required to fill these cells, the importance of the liquid distribution on supports used in gas chromatography is readily apparent. In the event that the cells were not filled the surface tension of the liquids would determine the degree and completeness of the filling or covering of the holes, both primary and secondary. It

would be expected that if any holes were to be closed the secondary ones would be filled first. It is evident that this microstructure can be the cause of tailing as observed in gas chromatography, especially where high carrier gas flow rates are used.

The large variation in the size of the pores and their random arrangement readily explain the high effectiveness of the diatomite as a filter aid. It is apparent that particles as small as 0·1μ might be expected to be retained when the solution is passed through a bed of calcined diatomaceous earth.

It should probably be emphasized that the kind of diatoms which are related to the location of diatomite deposits and the temperature and length of firing would all have some influence on the cell and pore sizes. These are therefore important considerations in the efficiency and use of 'Chromosorb P' as a gas chromatographic support.

BOOK REVIEWS

LAISSEZ-FAIRE, LAISSEZ DETRUIRE

Man and Environment

Crisis and the Strategy of Choice. By Robert Arvill. (A Pelican Original.) Pp. 332+13 photographs. (Harmondsworth, Middx.: Penguin Books, Ltd., 1967.) 8s. 6d.

MUCH that we admire in the English landscape—the trout stream, the parkland of the great estate, the grouse moor, the college garden, the mixed farm of arable and grassland, thick hedges and planted coverts-was created for the benefit of the few. It was created generally by an autocratic minority for their exclusive use and enjoyment in perpetuity and was deliberately designed, often with protective measures bordering on the ferocious, to exclude

Modern democratic principles insist, and rightly, that recreation in the widest sense and the enjoyment of the whole environment shall be the preserve of the whole nation. The increased leisure, the affluence, the train (as Wellington tactlessly pointed out) and latterly the car enable millions to travel to places where 50 years ago only a few could afford or were entitled to penetrate. I believe that the countryside will have to become, as the theatre and football match have become, a place of restricted entry unless it is to be destroyed by the multitude. Payment for entry to a National Park will have to become as commonplace as payment to enter any other place of entertainment.

The increase in population of the British Isles, or of other affluent countries for that matter, is only a trivial actor in the increase in pressure on the countryside. It s widely, but erroneously, assumed that were our population stabilized at, say, the 1900 figure no problems of vandalism, waste disposal, air and water pollution, housng pressures on land and all the other nastiness associated with industrial societies would arise. They would, in fact, all occur, but at a marginally lower rate. The principal ressures are industrial demands, ever increasing standards of individual affluence and leisure time, increased energy equirements, the spread of democratic principles and, bove all, the invention of the car.

Mr Arvill investigates in great detail the effect of these ncreased pressures on the air, the water and the wildlife opulations of our countryside. He places, I think, too such emphasis on the problem of population pressures nd insufficient on some of the other villains of the piece. Te makes excellent suggestions for immediate and future onservation and does not make the common mistake of elieving that conservation consists of putting a fence round certain animals and plants with a label saying Keep Out". He believes, as we must all come to believe, at conservation is the antithesis of preservation and nould comprise a mutual adaptation of the environment ourselves and ourselves to the environment. He does, think, less than justice to the planners in Britain, who, the past 20 years, have housed more people, accomodated more industry and permitted more exploitation the environment with less relative damage than virally any other country in the world. This is some compense for the unlimited and uncontrolled damage flicted in the 150 years up to 1939.

The book has an excellent bibliography with a catholic ste, a good index and a high standard of production roughout. I do not think that, with his condensed text d unlimited homework, Mr Arvill will achieve many nversions, but he will certainly educate, encourage and ovide ammunition for the converted. B. E. JUNIPER

HISTORIES OF TECHNOLOGIES

Technology in Western Civilization

The Emergence of Modern Industrial Society Earliest Times to 1900. Vol. 1. Edited by Melvin Kranzberg and Carroll W. Pursell, jun. Pp. xii+802. (London and New York: Oxford University Press, 1967.) 68s. net.

THE editors of this volume have attempted, with considerable success, to move forward from the tradition of encyclopaedias in the history of technology towards a viable textbook. The very definition of "technology" is nearly impossible, and whatever it is, it has complex relations with the whole of human activity and thought. so that a satisfactory history will require a great scholar as yet unknown. In default of that, the editors have at least produced a scheme of organization from which some historical understanding can be derived; and within its framework they have obtained essays of generally high quality from their specialist contributors. Implicitly acknowledging the contemporary interests of their audience (in the first instance, the US Armed Forces Institute), they assign bulk and detail in proportion to the historical proximity of the periods studied; thus the past two decades of the nineteenth century receive just as much space as all history to 1600. Within the limits of space of each period, they provide studies of the social. economic and cultural aspects of technological history. For the more recent periods, when the authors do not need all their space to review the well worn generalizations, this material can be illuminating.

But one is still left with a multi-layer sandwich. There are the good histories of particular technologies (divided up in a traditional scheme) and the good discussions of the preconditions and effects of technological change in the economic and social spheres. But, with the partial exception of the most recent period, there is little attempt to capture the flavour of the technical endeavour of any period. One cannot but compare this work with Klemm's History of Western Technology, which makes no claim to comprehensiveness, but which gives a vivid picture of the conception of technology in various milieu, through its carefully chosen extracts from original sources. textbook for an advanced course in the history of technology of recent times, this volume serves well; but for an introduction to this most important and most difficult sort of history, one will still fall back on Lilley, Mumford J. R. RAVETZ or Klemm.

FUNGI NEAR MR MacGREGOR'S GARDEN

Fungi, Wayside and Woodland By W. P. K. Findlay. Pp. xi + 202 + 50 plates. (London and New York: Frederick Warne and Co., Ltd., 1967.) 65s. net.

In the past fifteen years a considerable number of books. richly illustrated with coloured plates, have become available which help the field naturalist to identify the larger fungi. This book in the "Wayside and Woodland" series adds to their number, but it has a special quality because rather more than half of the forty or so coloured plates are the work of Beatrix Potter. It may come as a surprise to many that she was a serious and knowledgeable amateur mycologist, and indeed in the nineties of last century read a paper to the Linnean Society on the germination of agaric spores. But the environment of her books, which with the Bible and Shakespeare have played such a formative part in the literary style of my generation, is not so different from the habitat of toadstools. Peter Rabbit and his sisters who, it will be remem-"lived with their mother in a sandbank, under the root of a very big fir-tree" must have admired Russula emetica and many another in the autumn as they "went into the fields and down the lane" with strict orders to

avoid Mr MacGregor's garden.

To Beatrix Potter's coloured pictures, many of which have the authentic touch of genius, have been added almost an equal number of excellent plates by R. B. Davis and E. C. Large. Around these illustrations, and ten half-tone photographic plates the reproduction of which leaves much to be desired, Dr Findlay has woven a text. The first six chapters form a readable introduction to the larger fungi which the amateur will read with profit and which will give him added pleasure as he strolls through the woods in autumn casually trying to match the fungi he finds with the pictures in the book. The seventh to sixteenth chapters are devoted largely to the descriptions of individual species. The descriptions are simple and reflect Dr Findlay's profound knowledge of fungi. They are, however, clearly not intended for the more serious student and references to microscopic features and spore measurements have been avoided.

Perhaps the weakest parts of the book are the half-dozen black and white figures. For example, Fig. 3 gives a very poor and misleading picture of the beautiful microscopic structure of the hymenium in toadstools. It is easy, however, to criticize a work of this kind, but on the whole it is to be welcomed more on artistic and nostalgic rather than on scientific grounds, for all the time in appreciating Beatrix Potter's artistic skill in depicting a toadstool we can almost see Mr Jeremy Fisher or Squirrel Nutkin peeping round the corner. It is a pity that the book is so expensive that few individuals will be able to afford it.

C. T. Ingold

AN EXPANDING TECHNOLOGY

Progress in Microbiological Techniques

Edited by C. H. Collins. Pp. ix +231. (London: Butterworth and Co. (Publishers), Ltd., 1967.) 55s.

This collection of eleven papers reports contemporary developments in some of the more fascinating and sophisticated techniques used by microbiologists and those working in related fields. The editor of this volume, C. H. Collins, has selected a broad range of techniques for discussion, including several which are of direct relevance

to the applied microbiologist.

Clear, critical accounts are given of complement fixation, serological analysis of fungi and actinomycetes, fluorescent antibody methods and the freeze-drying of micro-organisms. Some specific needs of industrial and public health laboratories are considered in chapters on the microbiological assay of vitamins and amino-acids, standardization of vaccines, evaluation of yeasts and moulds for brewing and antibiotic production, phage typing of staphylococci and the examination of water supplies. This last chapter contains a particularly good appraisal of membrane filtration procedures and comments on the respective merits of currently available membranes. Most of the contributors direct their readers to sources of materials demanded by the methods described, whether they be items of equipment, reference cultures or serological reagents. One of the expressed hopes for this book is that it will be useful to microbiologists who may be required occasionally to apply any of the techniques discussed to their own peculiar problems. It is essential, therefore, to have a rapid and reliable reference to appropriate suppliers and this exigency is met almost to the full. Progress in Microbiological Techniques will also make valuable reading for teaching purposes and the chapter on the analysis of the bacterial cell gathers together an abundance of useful practical information. This book can be recommended strongly and any adverse criticism is slight and minor. One hopes that the producers of the present volume will be encouraged to think of it as the forerunner of others that will continue to survey, at a reasonable price, the development and application of new and specialist techniques.

ALAN T. BULL

LEARNING BY PROBLEM SOLVING

Problems and Solutions in Mathematical Physics

By Y. Choquet-Bruhat. Translated by C. Peltzer Translation edited by J. J. Brandstatter. (Holden-Day Series in Mathematical Physics.) Pp. ix+314. (Sar Francisco, London and Amsterdam: Holden-Day, Inc. 1967.) \$10.00.

This attractive book is aimed at introducing students of theoretical physics, applied mathematics, and engineering to some of the modern mathematical methods and concepts. It is not a book of rules of what to do, and it will appeal more to those people, both undergraduate and graduate, who care about what they are doing. The treatment is more rigorous than will appeal to some readers, though there is no undue emphasis on achieving the utmost generality; the work is essentially as simple as is compatible with ensuring the right answers.

There are 125 separate problems, many split into about five related parts, with full solutions. One of the first things to strike one is the great variety of topics covered. A list of the eight main section headings will give a rough idea of its scope: (1) Linear mappings. Operations on matrices. (2) Proper values and proper vectors. Reduction of matrices. (3) Scalar product and norm. Hermitian operators. (4) Vector calculus. Multiple integrals (5) Function spaces and operators. (6) Series expansions of functions. (7) Differential equations. (8) Partia differential equations. Some especially interesting features are the use of differential forms in parts of section 4, for example in a problem involving covariant derivatives and symmetries of the Riemann-Christoffel tensor, and the use elsewhere of the theory of distributions.

I found the problems interesting and well chosen Nearly all make a useful point or illustrate some importan principle. The solutions are helpful and seem generally though not universally, correct. Some of the English translation reads rather awkwardly, but there are few places where the meaning is not immediately clear. On certain pages there are quite a lot of trivial misprints—sixteen on page 217. In some cases these defects, or in complete explanations or definitions, make it difficult to interpret the question without first looking at the solution. The matter referred to in some footnote references for example, "... (see Problem Paris 1957)", on page 248, could not be found. Although the table of content lists every problem by name, a subject index would stick have been useful.

Even with the defects mentioned here, this seems to be a useful addition to the problem books of mathematical physics, and provides an enjoyable an interesting way of learning an important branch of the subject.

A. Weinmann

CHARGE CARRIERS IN ORGANIC SOLIDS

Organic Semiconductors

By Felix Gutmann and Lawrence E. Lyons. (Wiley Serie on the Science and Technology of Materials.) Pp. xvii 858. (New York and London: John Wiley and Son 1967.) 224s.

MODERN interest in the semiconducting properties organic crystals started about 20 years ago, with measurements on phthalocyanine crystals, first as powders, the as single crystals. The work was chiefly initiated

chemists for a variety of reasons, such as an interest in the light stability of dyestuffs, catalytic properties of conjugated compounds, or properties of polycyclic aromatic compounds in relationship to coal. The workers lent heavily on the broad theoretical ideas of the physicists, and still do. The physicists found germanium hard enough to understand, without branching out to consider organic substances, principally of ill defined purity. The additional stimulus of Szent-Gyorgyi's speculation on biochemical mechanisms in 1942 led to work on proteins and nucleic acids, and these biological aspects were first discussed at a Faraday Discussion at Nottingham in 1959. Around 1956 the relatively high conductivity of crystals of organic charge transfer complexes was discovered. An extra stimulus came in about 1960 when the Russian work on the semiconducting properties of heat-treated polyacrylonitrile appeared, and a great spate of work followed on polymers, of varying degrees of defined structure and purity. About this time also, precision pulse photoconduction measurements started on zone-refined anthracene and similar compounds. As a result of this work a good deal is now known about the way the various molecular energy states are involved in anthracene photoconduction, the effects of adsorbed oxygen and so on. Although a number of patents have been taken out in the field, many referring to electrophotography and one to possible superconduction, a major practical achievement is still awaited. On the biological side there are now a good many suggestions as to the involvement of electronic conduction in a number of biological processes, from photosynthesis to bone growth, without any conclusive proofs so far. (A discussion on the biological properties is planned for Nottingham in April 1968.)

With so much initial activity complete, we must extend a particular welcome to the present volume, by two Australian authors well known in the field. The treatment is as comprehensive as possible, and covers all the available literature, to the end of 1965; I detected only one or two gaps, in the Russian and Chinese references. An initial chapter outlines the basic notion of solid state physics which underlies the field of activity. Then follows an account of experimental methods and sample preparation. A fourth chapter deals with "Band Theory in Molecular Crystals", a fifth with excited states, and a sixth with ionized states. Finally, the tunnelling and nopping models are considered, the published data reviewed, parallels drawn between semiconductivity and structure, and the effect of space charges outlined. ast chapter comprises "Retrospect, Outlook and Speculation", and summarizes the present state of the art.

The book is to be praised for the comprehensive and accurate fashion in which it summarizes experiments and liscusses theories. The account is well balanced as well as encyclopaedic in character. No attempt is made critically to evaluate and distinguish the different approaches. and it may be argued that it is still too early for this to e a fruitful process. So far as can be judged the tables of data are reliable at all points. This is a book for all who contemplate research in the field. The authors leserve praise for their great effort of compilation, and he result is strongly recommended. D. D. ELEY

CARBONATE ROCKS

Carbonate Rocks

Origin, Occurrence and Classification. Edited by George Chilingar, Harold J. Bissell and Rhodes W. Fairbridge. Developments in Sedimentology, 9A.) Pp. 471. (Amsteram, London and New York: Elsevier Publishing Com-

HIS volume, together with Volume 9B in this series, is esigned to provide an overall treatment of carbonates.

Almost half (177 pages) of the book is devoted to two papers under the joint authorship of G. M. Friedman and J. E. Sanders ("Origin and Occurrence of Limestones" and "Origin and Occurrence of Dolostones"). Together these provide a valuable survey of much recent work within the area of reference. Some information is drawn from the authors' own experience (published and unpublished), but reference to 741 papers, from European, American and other sources, some of which are comparatively inaccessible, is an indication of their familiarity with, and presentation of, a very large volume of literature.

The same cannot be said of sonle other contributions. Fewer works are referred to by Y. Gubier, J. P. Bertrand. L. Mattavelli, A. Rizzini and R. Passega ("Petrology and Petrography of Carbonate Rocks"); due acknowledgement is not given to the dominant American influences on contemporary thought (economic and

academic) in this area.

A different criticism might be levelled at H. J. Bissell and G. V. Chilingar ("Classification of Sedimentary Carbonate Rocks"). The authors display a commendable lack of partiality, but a more systematic approach, such as that in one of the recent reviews of carbonate classification which they themselves recommend, would have been desirable. The new system proposed is not a radical departure, and is unlikely to meet with wide support. The article is nevertheless necessary to the volume and the authors provide many references and pertinent comments.

Other contributions by W. H. Taft ("Modern Carbonate Sediments") and J. W. Harbaugh ("Carbonate Oil Reservoir Rocks") also provide useful summaries. Harbaugh emphasizes the increasing commercial importance of both the physical-petrological and biological-ecological approaches to reservoir evaluation, and the interdependence of such factors with the environmental conditions in which the rocks were deposited.

"Carbonate Rocks and Palaecelimatology in the Biochemical History of the Planet" (R. W. Fairbridge) is concerned with the wider implications of carbonate sediments and environments. The geochemical, custatic and tectonic controls of carbonate sediments make them an exceptionally interesting field for large scale geological speculation.

In some ways the book is a disappointment: chapters are not all of the same standard, plates are not always relevant, and the introduction reviews at too great a length the subsequent chapters, themselves reviews. The surveys (particularly those by Friedman and Sanders) and references contained in them are, however, likely to prove of continuing use to the specialist and to those seeking a more general background to the ever-growing literature. C. J. R. BRAITHWAITE

SUBJECTIVE TIME

Psychological Time in Health and Disease

By John Cohen. (A Monograph in American Lectures in Living Chemistry.) Pp. xv+103. (Springfield, Ill.: Charles C. Thomas, Publishers, 1967.)

THE relationship between psychological time and physical or clock time has been the subject of philosophical speculation for many centuries. The study was put on a more scientific footing by the early experimental psychologists. but the area has been curiously neglected for the past 50 years. Professor Cohen's monograph may thus serve as a useful introduction to the psychology of time perception, either for those who are interested to discover what kind of work has been done or for those who are contemplating carrying out work in the area.

There is mounting evidence that many biological rhythms are controlled by internal "clocks" or "pacemakers" and, in his first chapter, Cohen examines the likelihood that the clusive time sense in man is mediated by such a clock. It does seem in fact that short-term changes in temperature or in arousal can modify the clock's speed and thus our estimates of time. Other factors such as attention, personality-type and emotion also seem to be involved, but few of the studies cited in the present book have been successful in assessing their relative roles.

Further chapters examine perception of small units of time and the broader concepts of past and future. The dependence of temporal judgements or the spatial position of stimuli is well illustrated by Cohen's own experiments. A chapter on aberrations of psychological time deals with the effects on mental illness, hypnosis and drugs and there is a chapter on subjective time in myth and literature which, if it does not give many scientific insights, has at least some pleasing illustrations. In a final chapter, Cohen integrates previous suggestions with his own ideas into a speculative model of time perception.

The strength of the monograph is that it is clearly and entertainingly written and may stimulate readers to seek out the original papers. Its weakness is that it is just too short and superficial to rate as a useful contribution to the scientific literature. The title Psychological Time in Health and Disease sounds comprehensive enough, but the "disease" aspect is dealt with in only four or five pages. In a creditable attempt to produce a readable book it seems to me that Cohen has thrown scientific rigour out of the window. Certainly there is a lack of good experimental studies on time perception, but Cohen seems to prefer anecdotes to such laboratory evidence as there is. Thus in the section on drug effects, although a number of experiments have been reported, Cohen quotes De Quincey and Walter de la Mare.

In summary, this is a lucid and entertaining book, but while it may be rated an admirable attempt to bridge the two cultures it does not take us much further in our search for the time sense.

F. I. M. Craik

OBITUARIES

Professor C. F. Davidson

CHARLES FINDLAY DAVIDSON was born at Monifieth, Angus, on July 16, 1911. From Morgan Academy he entered University College, Dundee, as second bursar and graduated at St. Andrews University in 1933 with first class honours in geology and mineralogy. Even before graduation he had published or had in hand five papers on the geology of his countryside and on an olivine-bearing conglomerate from Raasay in the Inner Hebrides.

In 1934 he was appointed assistant curator in the Museum of Practical Geology, and was responsible for the general displays on the ground floor of the new building in South Kensington to which the collections were being transferred before its opening in 1935. Private and official research in the period up to 1939 resulted in publication of "The Tertiary Geology of Rasasy" (1935), "A Contribution to the Geology of the Faroes" (with F. Walker, 1936), "Geology in the Museum" (with F. J. North and W. E. Swinton, 1941), several short papers such as "The Geology of the Coronation Stone" (1937), and his main petrological work, "The Archaean Rocks of the Rodil District, South Harris" (1942–43), which earned him the D.Sc. degree of St. Andrews.

Refused permission in 1939 to go on military service, Davidson was made responsible for the safe-keeping of the museum against war incident, the building having become the headquarters of Civil Defence, London region. In 1940, however, he was largely absorbed in the preparation of confidential reports to military and naval

intelligence on the topographical and surface conditions, the geology and the mineral resources of overseas areas of actual or potential warlike activity. Some of these areas became well known later in the war: the Möhne Dam, Yugoslavia, the flying bomb sites of northern France. In 1941 he was required to prepare a précis of all available information on the uranium resources of the world, and increasing demand for more, and more precise information led to the establishment of a Geological Survey unit to work on the location, examination and preliminary assessment of radioactive ores in collaboration with the Ministry of Supply and the US Atomic Energy Commission. For this work Davidson travelled widely to remote places ranging from the Canadian arctic, by equatorial Congo and Rhodesia, South Africa, southern India, to Australia. Thus he gained the field experience, the mineralogical knowledge, and the basic technical knowledge of prospecting and preliminary development which enabled him to train staff and to organize the laboratory facilities necessary for rapid quantitative assessment of samples, for mineral identification, and for development of an entirely new branch of prospecting science. In this task he was fortunate to have the support and advice of his director, W. F. P. McLintock. result of his experiences was the publication in 1949 of The Prospector's Handbook to Radioactive Mineral Deposits, which by the end of 1950 had sold more than 10,000 copies. The field work which he undertook in 1945 jointly with a South African and an American geologist led to the discovery of the uranium resources of the Witwatersrand bankets, to a meeting with Dr Jan Smuts, Prime Minister of South Africa, and to the inauguration in October 1952 of the new South African industry for the extraction of uranium. Davidson was in the forefront of the exploration and assessment of radioactive deposits in the Rhodesian copperbelt, at Radium Hill, South Australia, Blind River, Canada, and Travancore, India, and in the study of the rare elements in the granites and carbonates of many regions in Africa. While carrying out these field investigations he also supervised the development of new techniques for mineral identification and, in collaboration with physicists of the Atomic Energy Research Establishment, for the evolution of electronic instruments for mobile reconnaissance, as well as for detailed individual surveys, more precise laboratory evaluations of uranium and thorium content, and for borehole logging. For such outstanding service he was awarded the O.B.E. in 1953.

Later in 1953 he was invited to become professor of geology and mineralogy in his own university and accepted gladly. In his inaugural address he reviewed progress in the study of ore deposits since the time of Agricola and revealed the intensity of his concern with the search for minerals in the service of mankind. The change to academic life necessarily curtailed opportunity for practical work but afforded leisure—though leisure is not word properly applicable to Davidson-for reading and cogitation, and he devoted much time to the study of current Russian books and research papers on mineralogy ore genesis, and geochemistry, contributing longer and shorter critical reviews of them in Economic Geology, for the benefit of English-speaking geologists. His wide ranging study of the literature of modern field and laboratory investigations and his own experience combined to produce original conceptions of the origin of the gold and uranium in the South African bankets, of th accumulation of strata-bound ores through the agency of ascending brines, and of the genesis and epoch of the formation of diamonds in kimberlites. These were conceptions which provoked sharp controversy. Davidson publications, under his own name and in collaboration with his colleagues of the Atomic Energy division of the Ged logical Survey, on the association of uranium with hydre carbons and with phosphorites; on the application c isotope ratios to age determinations particularly relating

to the Pre-Cambrian rocks and of Recent fossil bones. and on the mineralogy of natural radioactive substances, are too numerous to itemize. But it is important to mention his numerous popular expositions of radiogeology and the place of geology in human progress, for his facility of lucid presentation rivalled that of the old masters of geology. Davidson's capacity for organization, his ready acceptance of responsibility, and his complete indifference to his own well-being in the course of duty were well known to his colleagues. They became apparent to an international gathering in the success of the recent symposium which he organized in St. Andrews at extremely short notice on behalf of the International Association on the Genesis of Ore Deposits. On the evening of his death he had been busy with proofs of the 50 papers and the proceedings of the meeting. Few men can have lived so full a life and so greatly enjoyed the living of it.

Professor James P. Todd

Professor Todd, who died on November 10, was appointed lecturer in pharmacy in the Royal Technical College, Glasgow, in 1921. In 1937 he became the first professor of pharmacy in the United Kingdom, in the same college. From modest beginnings, his work so prospered that he leaves to his successors a great school of biological sciences with more than four hundred students, a large staff qualified in a wide range of scientific disciplines, and eight academic chairs all tracing their foundation directly or indirectly to his inspiration.

A native of Glasgow, James Todd attended Albert Road School and received his early training in the old Glasgow and West of Scotland School of Pharmacy. His military service in the Medical Corps during the First World War in South Africa, India and Iraq gave him an insight into some of the problems of tropical medicine. After the war he resumed his studies and was awarded the qualification of Ph.C. in 1921. In collaboration with the late Professor Ellis, he then helped to establish the first degree course in pharmacy in Britain under the relevant ordinances of Glasgow University. The first students were enrolled in 1924. In the meantime, and often in difficult conditions, he commenced his personal research into the properties of the digitalis drugs which later led to his award of the degree of Doctor of Philosophy by Glasgow University.

His subsequent research always concerned practical problems of medical science and covered a wide field. During the Second World War the Department of Health for Scotland sought his help in preparing pyrogen-free saline infusion fluids, and this led to his contributions in the field of bacterial pyrogens. His work on blood transfusion led to the establishment of the West of Scotland Blood Transfusion Service. For many years he was

honorary director of this service.

War problems also attracted him to study the treatment of burns (in collaboration with the Medical Research Council, then established at the Royal Infirmary). This work, in turn, brought him into contact with the problems of plastic surgery. The establishment of the chair of bioengineering at Strathclyde can be traced directly to these early contacts with Mr T. Gibson, the plastic surgeon, who first sought his advice in attempting to find means of bringing science and engineering to bear on the practical work of the operating theatre.

After the war Todd served on a working party set up by the Minister of Food to examine the provision of facilities for the training of young people in the study of the properties and processing of foodstuffs. British vulnerability to food shortage had been highlighted during the war, and after consultations with the experts in this field Todd concluded that this subject merited designation as a scientific discipline in its own right. He established an associateship course (at honours degree level) and described the field of study as "Food Science". This was

the first course of its kind in the United Kingdom, and is believed to be the first use of this term applied to a degree level course in the world. This course led to the establishment of the chair of food science at Strathelyde in 1958, and the term food science is now used internationally and on both sides of the Iron Curtain.

For a man who has been the focus of so much initiative in pharmacy, food science, microbiology, pharmacology, pharmaceutical technology, biology and biochemistry, Todd was no academic tycoon. Unassuming in manner, his kindly, simple and tolerant ways disguised a fixity of purpose which was only apparent to those who knew him well, or who had the misfortune to oppose his vision. In these days when it is often difficult to distinguish a professor from a business man, he was one of the last of the great race of university characters. Of course, his unorthodoxy bred opposition. Time and again the ranks would close against him, only to find themselves outflanked by his mental and administrative dexterity. If his opponents were sometimes a little bewildered as to how he achieved his ends, they learned to respect him by his success.

He devoted countless hours to the Pharmaceutical Society, served on expert committees, worked as an examiner and, above all, made behind-the-seenes contributions to the establishment of the University of Strathelyde. This must wait for later appraisal, but it is pleasant to record that in 1964 his services to medicine were recognized by his election as an Honorary Fellow of the Royal College of Physicians and Surgeons, Glasgow.

J. HAWTHOEN

Professor Douglas McKie

ONE of Britain's leading historians of science died on August 28, 1967. The son of a Scot, Douglas McKie was born on July 15, 1896, in Tredegar, Monmouthshire, where he was educated at the Grammar School. Intending to be a regular soldier, he entered Sandhurst and served as a lieutenant on the Western Front until he was severely wounded in 1917. He became a chemistry student at University College, London, in 1920, graduated in 1923, and in 1927 obtained his Ph.D. under F. G. Donnan for research on gas adsorption.

Already interested in military history, McKie soon acquired a taste for the history of science, and in 1925 he became a part-time assistant in the new Department of History and Philosophy of Science (as it is now called) at University College, London. A full-time appointment followed, and eventually, from 1957 to 1964, he was

professor and head of the department.

McKie will be chiefly remembered for his studies of seventeenth and eighteenth century theories of heat, combustion and related topics; of the men responsible for the advances in this field; and of the institutions to which they belonged. Only his principal works can be mentioned here. In 1935, he published The Discovery of Specific and Latent Heats (with N. H. de V. Heathcote) and Antoine Lavoisier, the Father of Modern Chemistry, which contains a detailed account of Lavoisier's chemical researches. There was then no British periodical devoted to the history of science; McKie was a founder of Annals of Science, and as its principal editor from 1936 until his death he exercised a great and beneficial influence on the subject. Early volumes contain his masterly series of "Historical Studies in the Phlogiston Theory" (with J. R. Partington) and the first part of his long study of Black's unpublished chemical lectures, completed only in 1967. He was also a foundation member of the Society for the Study of Alchemy and Early Chemistry; his account of the combustion theories of Boyle, Hooke and Mayow is in Volume 1 of its journal, Ambix.

During the 1939-45 war, McKie was attached to the Department of Chemistry of University College, but he found time to publish in 1942 a valuable account of

Newton's chemical theories. He wrote several papers about Priestley, but in later years he concentrated on the French and Scottish schools. All aspects of Lavoisier's eareer are considered in Antoine Lavoisier, Scientist, Economist, Social Reformer (1952), and McKie was largely responsible for negotiations leading to the preservation in France of Lavoisier's apparatus. For this and other services to the Académie des Sciences he was appointed Chevalier de la Légion d'Honneur. The Royal Society is also indebted to him for a detailed discussion of its origins, published in 1960. A lover of books, McKie had a great knowledge of the bibliography of science, and he wrote scholarly introductions to reprints of works by Rey, Boyle and Lavoisier, and to a finely produced transcript of a set of notes taken during Black's lectures.

McKie was one of the first full-time historians of science in any country, and he lived to see the subject attain full academic and professional status. He received many honours, but he probably derived most satisfaction from the knowledge that former students of his department are now teaching the history of science in universities, colleges and schools throughout Britain and also overseas.

W. A. SMEATON

University News:

London

DR E. H. Andrews, reader in science of materials at Queen Mary College, has been appointed to the chair of materials tenable at that college.

Appointments

PROFESSOR MICHAEL ABERCROMBIE has been appointed director of the Strangeways Research Laboratory as from July 1, 1970. He will succeed Dame Honor Fell.

The following appointments have been made to the World Meteorological Organization Secretariat: Dr Kaare Langlo, at present chief of the Technical Division, is to be director of the Scientific and Technical Department; Dr Hermann Sebastian, at present chief of the Technical Co-operation Division, is to be director of the Technical Co-operation Department; Dr G. G. Tarakanov, at present special adviser on scientific matters to the secretary-general, is to be special assistant to the secretary-general for technical policies and programmes; Mr B. Zavos, at present chief of the Planning and Co-ordination Group at the National Environmental Satellite Centre, Environmental Science Services Administration, Washington DC, is to be special assistant to the secretary-general for World Weather Watch Management and Co-ordination.

Announcements

The following have been made honorary fellows of the Royal Aeronautical Society: Sir George Dowty, chairman and managing director of the Dowty Group Ltd., in recognition of his services to aviation, especially in the design and development of aircraft accessory systems; Professor H. J. Van Der Maas, professor of aeronautics at the Technological University of Delft, in recognition of his contributions to aeronautics, especially in advancing international co-operation and goodwill; Dr Barnes Wallis, chief of the Department of Aeronautical Research and Development, BAC (Operating), Ltd., and special director, BAC Weybridge, for his contributions to aeronautical design over many years.

The first Louisa Gross Horwitz Prize for basic research in biology or biochemistry has been awarded by Columbia University to Dr Luis F. Leloir, at present director of the Institute of Biochemistry of the Campomar Foundation and head of the Department of Biochemistry in the University of Buenos Aires. The prize of \$25,000 was given in recognition of his discovery of the nucleoside diphosphate sugars and the demonstration of their important role in the biosynthesis of sucrose, the plant starches, liver glycogen and other polysaccharides.

CORRESPONDENCE

No More Coal

SIR,—The comments on the coal industry in your issue of November 18 (Nature, 216, 627; 1967) may give a misleading impression of the future of this industry and of the attitude of those responsible for its leadership. One chronic problem facing the NCB is that while we are in the middle of a productivity and rationalization drive—which we are winning—we are continuously subjected to press comments which can only damage confidence in the industry's prospects.

We spend about £5 million a year on our research and development programme. There are some extremely exciting projects, especially involving new uses for coal and the up-grading of by-products and waste materials. To succeed in these projects we need not only a steady flow of good scientists, but also the interest of scientists outside the industry who may be able to help us.

We submitted a memorandum on these aspects of our research and development programme, covering our utilization and diversification activities, to the House of Commons Select Committee on Science and Technology. I enclose a copy of this and would be glad to supply one

to anyone who cares to write to me.

Your heading "No More Coal" is, of course, belied by the figures included in the White Paper Fuel Policy (now being revised because of devaluation), and Mr Richard Marsh, the Minister of Power, has himself always been at great pains to emphasize what a large industry this will be even in the light of the White Paper forecasts. For example, between now and the end of 1980 at least 1,500 million tons of coal will be required and the turnover of the industry will total something like £10,000 million, with our increasing diversifications. But the NCB does not accept the inevitability of the decline forecast in the White Paper You say that the White Paper figures on nuclear power "might almost convince Lord Robens". The figures to which you refer, however, are merely a new set of calcula. tions, admittedly of greater sophistication, but they are not based on any more positive evidence about the presumed performance of the AGR nuclear power stations Now that the Select Committee Report has been published our attitudes and arguments are fully available and would justify the closest consideration by all scientists and engineers. It is most important to appreciate that our case is not by any means related merely to social considerations, important—and expensive—though these We believe that coal can still be economically competitive throughout the 1970s.

Arguments for this belief and the reasons why previous studies have in our view been inadequate are complex. In the Select Committee Report there are three contributions from the NCB which set out the position. The last of these—and indeed the last page in the Report—ends as follows: "Conclusions. In view of the technical and economic doubts about the future performance of AGE stations, the NCB think that the proper course is now for an independent technical expert to make a full assessmen of the nuclear power programme, supported by as independent for a significance of the stations.

independent financial assessment."

We should obviously not be asking for such an examination if we were not fully confident that our views would be sustained.

Yours faithfully,

L. GRAINGER
Member for Science,
National Coal Board.

National Coal Board, Hobart House, Grosvenor Place, London, SW1.

FORTHCOMING EVENTS

* (Meetings marked with an asterisk are open to the public)

Monday, December 11

UNIVERSITY OF LONDON (at Queen Mary College, Mile End Road, London, E1), at 4.30 p.m.—Professor R. L. Martin (University of Melbourne): "Some Recent Aspects of Inorganic Chemistry".*

INSTITUTION OF MECHANICAL ENGINERS, HYDRAULIC PLANT AND MACHINERY GROUP—FLUID MACHINERY SECTION (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p.m.—Discussion Meeting on "Glandless

INSTITUTION OF ELECTRICAL ENGINEERS, LONDON GRADUATE AND STUDENT SECTION (at Savoy Place, London, WC2), at 6.30 p.m.—Sir Stanley Brown: Presidential Address.

Monday, December 11-Saturday, December 16

UNIVERSITY OF CAMBRIDGE, SCHOOL OF CLINICAL RESEARCH AND POST-GRADUATE MEDICAL TEACHING (at Churchill College, Cambridge)—Introductory Course on "The Biology of Skin".

Tuesday, December 12

ROYAL INSTITUTION (at 21 Albemarle Street, London, W1), at 1.15 p.m.—Professor R. King: "Faraday's Contribution to Electrochemistry".*

ZOOLOGICAL SOCIETY OF LONDON (at the Zoological Gardens, Regent's Park, London, NW1), at 5 p.m.—Scientific Papers.

INSTITUTION OF ELECTRICAL ENGINEERS (joint meeting with the Automatic Control Group of the Institution of Mechanical Engineers, at the Institution of Electrical Engineers, Savoy Place, London, WC2), at 5.30 p.m.—Professor H. H. Rosenbrock: "The Gap Between Multivariable Theory and Practice".

INSTITUTION OF MECHANICAL ENGINEERS, AUTOMOBILE DIVISION (at 1 Birdcage Walk, Westminster, London. SW1), at 6 p.m.—Mr W. A. Crago: "Problems Associated with the Use of Skirts on Hovercraft".

INSTITUTION OF ELECTRICAL ENGINEERS, JOINT I.E.E./I.E.R.E. COMPUTER GROUP (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, WCI), at 6 p.m.—Mr P. Cox, Mr V. J. McMillan and Mrs D. Crook: "The Rvaluation and Prediction of Equipment Reliability".

Wednesday, December 13

GEOLOGICAL SOCIETY OF LONDON (at Burlington House, Piccadilly, London, W1), at 5 p.m.—Mr G. Vallance and Mr R. A. Fortey: "A New Ordovician Fauna from Spitsbergen" (Demonstration): Dr R. Casey: "The Type-Section of the Volgian Stage (Upper Jurassic)" (Demonstration): Professor A. W. Skempton: "The Consolidation of Clays by Gravitational Compackion" (Paper).

ROYAL STATISTICAL SOCIETY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, WC1), at 5.15 p.m.—Mr A. R. Thatcher: "The Distribution of Earnings of Employees in Great Britain".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Discussion Meeting on "Breakdown of Liquids" opened by Professor T. J. Lewis.

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Mr A. J. Haselfoot and Mr A. Armstrong: "Design Features of a 240 MVA 275/132 kV Site-Assembled Autotransformer".

SOCIETY OF ENVIRONMENTAL Engineers (in the Mechanical Engineering epartment, Imperial College, London, SW7), at 6 p.m.—Discussion meeting "Environmental Engineers or Witch Doctors" opened by Mr J. Salter nd Mr H. Goldberg.

INSTITUTE OF INFORMATION SCIENTISTS (at Knightway House, 20 Soho Square, London, W1), at 6.15 p.m.—Mr R. E. Fry: "The GLC Research and ntelligence Unit".

Society of Chemical Industry, Food Group—Nutrition Panel (at 4 Belgrave Square, London, SW1), at 6.15 p.m.—Dr E. Kodicer and Dr P. Iwood: "Absorption of Nutrients".

Wednesday, December 13-Thursday, December 14

BRITISH CERAMIC SOCIETY, BASIC SCIENCE SECTION; and the MINERA-GGICAL SOCIETY, CLAY MINERALS GROUP (at the Royal Aeronautical Society, Hamilton Place, London, W1), at 10 a.m. daily—Meeting on "Clays and ther Colloidal Systems in Ceramica".

Thursday, December 14

CHEMICAL SOCIETY (at the Royal Institution, 21 Albemarle Street, London, 71), at 5 p.m.—Professor C. A. Coulson, FRS: "Symmetry" (Faraday ecture).*

INSTITUTE OF FUEL (in Lecture Room 220, Imperial College, Exhibition oad, London, SW7), at 5.30 p.m.—Professor Sir Owen Saunders: Melchett

INSTITUTE OF PETROLEUM, ECONOMICS AND OPERATIONS GROUP (at 61 ew Cavendish Street, London, W1). at 5.30 p.m.,—Mr D. A. Hammett: "The overcraft as a Special Purpose Vehicle".

Institution of Electrical Engineers (at Savoy Place, London, WC2), 5.30 p.m.—Mr A. Stark: "Computer Methods for Electrostatic Field etermination and Ray Tracing in Image Intensifiers".

Institution of Mechanical Engineers, Nuclear Energy Group (at Birdcage Walk, Westminster, London, SW1), at 6 p.m.— Discussion Meetgon "The Choice of Blower Drives for Nuclear Reactors".

SOCIETY OF CHEMICAL INDUSTRY, ROAD AND BUILDING MATERIALS ROUP (at 14 Belgrave Square, London, SW1), at 6 p.m.—Mr J. Weaver: ome Aspects of Materials for Concrete Roads".

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN (at 17 Bloomsbury Square, andon, WC1), at 7 p.m.—Mr G. R. A. Short: "Flavours and Colours in od and Pharmaey" (Harrison Memorial Lecture).

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE (at Manson House, 26 Portland Place, London, W1), at 7.30 p.m.—Professor W. E. Kershaw, Dr D. J. Lewis, Dr T. R. Williams and Dr B. O. L. Duke: Symposium on "Onchocerciasis—Entomological Aspects". Chairman: Professor P. C. C. Garnham, CMG, FRS.

Thursday, December 14-Friday, December 15

BIOCHEMICAL SOCIETY: and the SOCIETY FOR GENERAL MICROBIOLOGY (at the University of Leicester)—Symposium on "Control of Gene Function in Micro-organisms"; Ordinary Meeting for the presentation of communications; Demonstration Meeting on "Anaerobic Techniques and Multiple Inoculation Methods" and a Symposium on "The Teaching of Microbiology in Schools".

Friday, December 15

BRITISH INSTITUTE OF RADIOLOGY (at 32 Welbeck Street, London, W1), at 2.30 p.m.—Meeting on "Malignant Disease in Children".

INSTITUTION OF ELECTRICAL ENGINEERS, JOINT I.E.E./I.E.R.B. MEDICAL AND BIOLOGICAL ELECTRONICS GROUP, at the Institution of Electrical Engineers, Savoy Place, London. WC2), at 2.30 pm.—Discussion Meeting on "Applications of Thin Films and Integrated Circuits in Medical and Biological Instrumentation".

Saturday, December 16

INNER LONDON EDUCATION AUTHORITY (at the Horniman Museum, London Road, Forest Hill, London, SE23), at 3.80 p.m.—Dr Peter Ucko: "Art, Magic and Religion in the Old Stone Age".*

Monday, December 18

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Discussion Meeting on "Cabling for Difficult Industrial Environments" opened by Mr G. L. Leighton, Mr D. Balk, Mr D. J. Mills and Mr T. P. P. Balk T. B. Rolls

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Discussion Meeting on "Recent Developments of Inductive Ratio Standards", opened by Mr J. J. Hill.

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the

APPLICATIONS are invited for the following appointments on or better dates mentioned:

LECTURER (with special interests in ecology including population ecology, or ecological methodology or physiological ecology) in Botany at the University of Auckland, New Zealand—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mail, London, SWI (New Zealand and London, December 15).

LECTURERS/ASSISTANT LECTURERS (2) in SOCIOLOGY—The Secretary, University of Exeter, Northcote House, The Queen's Drive, Exeter, Devongation (December 18).

shire (December 18).

shire (December 18).

SENIOR LECTURER or LECTURER (with a science degree specializing in geology, considerable research experience, and preferably with a higher degree) in GEOLOGY at the University of Queensland, Australia. The Association of Commonwealth Universities (Branch Office), Martheorough House, Pall Mall, Loudon, SW1 (London and Brisbaue, December 20).

LECTURERS (2) in the DEPARTMENT OF CHEMICAL ENGINEERING—The Registrar, University College of Swansea, Singleton Park, Swansea, South Wales (December 23).

Registrar, University College of Swansea, Singleton Park, Swansea, South Wales (December 23).

Lecturer of Assistant Lecturer in Sociology—The Secretary of the University Court, The University, Glasgow (December 30).

Lecturer (with research interests in cell biology, especially its more molecular aspects) in the Department of Biophysics, School of Biological Sciences—The Registrar, King's College (University of London), Strand, London, WC2 (December 31).

Scientific Officer of Senior Scientific Officer (with a good homours degree in mathematics with some training in statistics, or a degree in statistics, and preferably an interest in computer programming)—The Secretary, ARC Institute for Research on Animal Diseases, Compton, near Newbury, Berkshire (December 31).

Glassblower in the School of Physical Sciences—The Registers, The New University of Ulster, Coleraine, Northern Ireland (January 1).

Research Fellow (organic chemist, with a Ph.D. or equivalent research experience) in the Department of Medical Research, Institute of Advanced Studies, Australian National University, to work on the synthesis and reactions of nitrogen heterocycles—The Association of Commonwealth Universities (Branch Office), Mariborough House, Pall Mall, London, SWI (Australia and London, January 1).

Senior Lecturer of Lecturer in the Department of History and Lecturer in the

Office), Marlborough House, Pall Mall, London, SW1 (Australia and Longou, January 1).

Senior Lecturer of Lecturer in the Department of History and Philosophy of Science (to be Head of the Department)—The Secretary. The University, Aberdeen (January 13).

Lecturers/Senior Lecturers (with a good university degree in mining engineering and experience in metalliferous mining of rock mechanics) in Mining Engineering, University of Queensland—The Association of Commonwealth Universities (Branch Office), Marlborough House, Pall Mall, London, SW1 (London and Brisbane, January 15).

Lecturer (preferably with an interest and experience in thermodynamics applied to high temperature reactions) in Chemical Thermodynamics—The Staff Officer (598/6), The University of Aston in Birmingham, Gosta Green, Birmingham, 4 (January 16).

UNIVERSITY LECTURERS and/or UNIVERSITY ASSISTANT LECTURES in PURE MATHEMATICS—The Secretary of the Appointments Committee of the Faculty of Mathematics, The University, Silver Street, Cambridge (January 16).

Faculty of Mathematics, The University, Silver Street, Cambridge (January 16).

I.ECTURER or ASSISTANT LECTURER in Physical Chemistry—The Registrar and Secretary, The University, Leeds, 2, quoting Ref. 68/24/1 (January 31).

LECTURER/SENIOR LECTURER (preferably with research experience or special interest in (a) plant physiology; (h) physiological ecology; and/or (c) cytology and histochemistry) in BOTANY at Massey University. Palemerston North, New Zealand—The Secretary-General, Association of Commonwealth Universities (Branch Office), Marlborough House, Pali Mall, London, SW1, or the Registrar of the University (New Zealand and London, January 31).

ASSISTANT EXPERIMENTAL OFFICER or EXPERIMENTAL OFFICER (with a degree or equivalent in a suitable subject, and training and experience in botany, agricultural botany or agricultural chemistry) for laboratory and glasshouse research to assess potentialities of new herbicides—The Secretary, ARC Weed Research Organization, Begbroke Hill, Kidlington, Oxford, quoting Ref. 17/67.

LECTURER/SENIOR LECTURER (graduate in metallurgy or physics) in PRYSICAL METALLURGY to give lecturer courses and pursue research in one or more of the following subjects: metal physics, modern physical metallurgy, crystallography—The Secretary, Sir John Cass College, Jewry Street, London, EC3.

lurgy, crystallography—The Secretary, Sir John Cass College, Jewry Street, Jondon, BC3.

Physicist or Engineer for research in high temperature plasmas and on supersonic combustion waves; work will involve advanced electronics and modern high speed optical recording—Professor A. R. Ubbelohde, FRS, Head of the Department of Chemical Engineering and Chemical Technology, Imperial College, London, SW7.

RESEARCH ASSISTANT (with a good honours degree in zoology and an interest in marine ecology) in Zoology—The Academic Registrar, Hatfield College of Technology, Hatfield, Hertfordshire.

TECHNICAL ASSISTANT (preferably with experience in chromatographic techniques) for RESEARCH INTO BILE SALT CHEMISTRY AND METABOLISM—Professor G. A. D. Haslewood, Blochemistry Department, Guy's Hospital Medical School, London Bridge, SE1.

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one or two copies of NATURE each week is:

*12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire	ch
United States of America(by air freight)\$48 ea	ch
Canada	ch
Elsewhere overseas by surface mail£14.0.0 ea	
(Charge for delivery by air mail on application)	

*Shorter periods pro rata. (Minimum three months.) MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered:

12 MONTHS (52 issues and 4 indexes)

Number of	G.B. &	U.S.A.	Canada	Elsewhere
Copies	Eire	(by air	freight)	(surface mail)
3–5 6–11 12 or more	Each £13.10.0 £12.15.0 £12.0.0	Each \$46.50 \$44.50 \$42.50	Each \$50.50 \$48.30 \$46.00	Each £13.10.0 £12.15.0 £12.0.0

Multiple subscriptions must run concurrently. Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address. (ZIP essential for U.S.A.)

NATURE Volume 216 DECEMBER 16, 1967

Slaughter or Vaccination?

THE most severe outbreak of foot and mouth disease ever to occur in Britain is at last being brought under some semblance of control. The Minister of Agriculture said in the early stages of the epidemic in October that the traditional slaughter policy—the slaughter of all livestock on infected farms and the prohibition of movement of livestock in infected areas—must be made to work. It seems as if it has. But in the process, three hundred thousand animals have been killedalmost one in every two hundred farms. The cost has been so great that the whole slaughter policy should be rigorously re-examined in the post-mortem that is bound to follow the final eradication of this epidemic. The British Government and the farmers must ask themselves if it is still realistic to try to fend off the disease by slaughtering and if it is not, what should be done instead.

Foot and mouth disease is not endemic in Britain. All infection comes from abroad. Obviously the best way to keep the country free from this disease would be to cut off the sources of infection. The source of the latest outbreak has yet to be identified, but the Gowers report in 1954 made it quite clear that contaminated meat imported from countries where the disease is endemic has been the chief source of infection. Migratory birds and tourists are blameless. Even so, successive British governments since 1954 have chosen to chance their luck and run the risk of foot and mouth disease rather than to ban meat imports from infected countries and suffer the commercial consequences that would follow. The decision which the Minister of Agriculture made last week to temporarily ban further imports of meat from South America and South Africa, which now has its own outbreak of foot and mouth disease, was a splendid illustration of how to shut the stable door after the horse has bolted. It certainly provoked an immediate reprisal from Argentina, which declined to buy racehorses at the Newmarket sales.

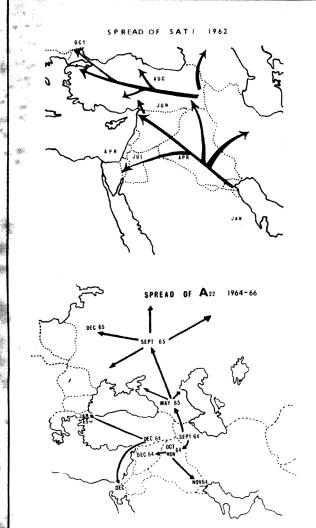

It is of course just possible that the British Government was being more subtle than usual. Is the temporary ban quietly going to become permanent? It is certainly difficult to believe the official reason for the ban, that veterinary resources could not stand up to another primary outbreak. Perhaps the government hopes that, once everybody is used to a temporary ban, this can be made permanent with the minimum of reprisals and this may be quite sensible. Even if

the latest outbreak did not originate in contaminated meat, it has shown just what havoc foot and mouth disease can cause and the folly of neglecting any measure which can reduce the risk of infection. To insist on a slaughter policy and do nothing to stop one of the sources of infection is to court disaster.

If it is decided that Britain simply cannot afford to lose cheap imported meat and perhaps export markets as well, better precautions must be taken to inspect imported meat. The existing arrangements are totally inadequate. There is also much to be said for increasing the penalties for the misuse of swill in the feeding of animals. Food waste like this often contains scraps of imported meat which should strictly be sterilized by boiling for at least an hour. The National Farmers' Union admits that some farmers may still feed unsterilized swill to pigs. If the penalties were increased, they would no doubt be more inclined to obey the law.

This week the National Farmers' Union began talks with the government about foot and mouth disease. Certainly if the slaughter policy is maintained, some form of compulsory national insurance to cover the consequential cost of foot and mouth disease, the loss of income which in the present outbreak the farmers may suffer for several months, should be considered. At present individual farmers can insure against the disease but few do so because of the high premiums and the fact that, in the past at least, it has seemed unlikely that a major outbreak would occur.

But the real question that has to be answered is whether or not Britain should use vaccination against foot and mouth disease. The current techniques of vaccination are admittedly not entirely satisfactory. This is hardly surprising. Countries such as the United States, Great Britain, Australia and New Zealand, which might be expected to finance large scale research into foot and mouth disease, use the slaughter policy. Countries where the disease is endemic are often less fully developed and lack the resources to devote to research. As it is, the Agricultural Research Council's Animal Virus Research Institute at Pirbright, with an annual budget of only about £0.5 m, has won a high international reputation for research into foot and mouth disease. The vaccines and vaccination techniques it has developed are used throughout the world except—ironically enough—in Britain, where the use and even the production of vaccine is illegal except

These two maps show the rapid spread of two sub-types of foot and mouth disease virus, SAT1 and A_{22} , in 1962 and 1964-66 respectively. In both epidemics the spread of the virus into Western Europe was prevented by vaccinating cattle at the Greek, Turkish and Bulgarian frontier region. A_{22} is, however, at the moment causing outbreaks of the disease in the Soviet Union and presents a great threat to the herds of Western European countries which, although vaccinated against the sub-type A_{3} , are susceptible to infection by A_{22} (ARC Animal Research Institute, Pirbright).

at Pirbright. British farmers are not free to import vaccine and use it, even if they are prepared to have their animals slaughtered. Vaccination is prohibited because, apart from the cost, there is the widespread belief, officially recognized by the Gowers report in 1954, that once vaccination is used the disease will become endemic.

But is this really so? It may have been the case in 1954, but since then better vaccines have been developed and workers at the Pirbright Institute, who should know more about foot and mouth diseases than most other people, believe that, given proper control, vaccination could be used without the disease becoming endemic. Dr Brooksby, the director of the Institute at Pirbright, for example, said last week that he did not believe foot and mouth disease was endemic in

France where vaccination is used. If the current epidemic had spread still further, vaccination would no doubt have been used to cordon off infected regions. This, after all, is why the government authorized the importation of five million doses of vaccine, costing £300,000.

A part of the argument against the use of vaccines is that animals carrying the disease would then be concealed in British herds. But carrier animals which have the disease but do not show clinical symptoms may appear in unvaccinated herds as well as in those which have been vaccinated. So the existence of carriers is really no argument against vaccination. Admittedly it is impossible to give pigs immunity by vaccination for any length of time with existing vaccines, but there is no reason why this should not be done if more effort and resources were put into research. Experiments in West Germany may well provide a means of doing this, but, even if they do not, there is no excuse for the belief that solutions are unattainable.

The argument that it is cheaper to slaughter all animals on infected farms than to vaccinate the national herd is true only so long as an outbreak is brought quickly under control. The Ministry of Agriculture claims that to vaccinate all cloven-hoofed animals in Britain would cost between £26-£50 million a year. This is likely to be an overestimate. £14 million has already been paid in compensation for livestock killed in this epidemic. But nobody, government or the farmers, has the slightest idea how much the so-called consequential costs have been. They are likely, in the long run, to exceed the amount paid in compensation. It is difficult to understand how the government can be certain vaccination is more expensive than the present policy when nobody knows just how much the real costs of the slaughter policy are. Some attempts should be made to devise a costing system to assess the cost of the slaughter policy in outbreaks of varying degrees of severity.

The most obvious losers and therefore the firmest opponents of vaccination are the breeders of pedigree livestock. They fear that, once vaccination is started, traditional markets in North America and Australasia will be lost. Breeding and exporting pedigree livestock seems to be involved with national pride, but the value of these exports is relatively trivial, running to between £2 million and £5 million a year and including a good deal of business with countries where foot and mouth diseases are endemic or where vaccination is used. But this is a seller's market, and countries which need British pedigree livestock to maintain the quality of their natural herds would quickly learn to accept vaccinated cattle. Even the spectre of the occasional carrier could be eliminated by the simple expedient of the Proband test.

In the circumstances, it is plain that the case against vaccination needs urgently to be re-examined. It is by no means as strong as received doctrine would suggest. The question of whether the national herd should be vaccinated is not the only one to ask. It is

also important to develop some feeling for the strategy of how vaccination could be used to contain outbreaks of foot and mouth disease. Much will depend on the improvement of vaccines and of techniques which the years ahead are certain to bring. Already there is a vaccine against three strains of the virus which costs no more than the univalent preparations available a decade ago. The authorities should seek more deliberately than in the past to exploit the new opportunities which are arising. There is also a strong case for believing that progress would be faster than it is if research were prosecuted more urgently. The epidemiology of foot and mouth disease cries out for more serious attention than it has so far received, and this is only one of the directions in which efforts should be encouraged.

There is also a strong case for a better co-ordination of national policies towards foot and mouth disease, especially in tightly knit and intensively farmed regions such as Europe, for foot and mouth virus has no respect for national frontiers. Above all, it is necessary somehow to throw off catatonic acceptance that foot and mouth disease can only be countered by slaughtering. There is too much similarity for comfort between the funeral pyres on British farms in recent weeks and the sacrificial flames with which the ancients sought to keep away evil spirits.

Hemispheric Queue

THERE is rough justice in the fact that British people wanting to emigrate to America in the next three years will find themselves at the end of the queue. What Congress intended when it liberalized the American immigration laws in 1965 was to end the system of choosing aliens on a basis of their country of origin, northern Europeans preferred, that had given offence around the world since 1921. The new law says simply, in President Johnson's words, "that those wishing to emigrate to America shall be admitted on the basis of their skills and their close relationship to those already here". The old British quota-65,361 a vear—the largest allotted to any country—was based on the fact that the British were the original settlers whose descendants formed the dominant ethnic group in isolationist post-world War I America. Not only did this generous quota mean that the British could emigrate to America on the spur of the moment, but also that about 35,000 visas a year were left unused.

But good intentions can backfire. The first big shock came when Congress realized that its new immigration law was a positive invitation to skilled and professional people from underdeveloped countries to join the brain drain. In the transition period between October 1965 when the bill was passed and next July, when it comes into full effect, unused portions of national quotas were transferred to countries with long waiting lists. Immediately the flow of loctors, scientists and engineers from Asia, Africa and South America jumped dramatically (the number of mmigrant visas given to Asian professionals nearly ripled between 1965 and 1966).

Now July 1968 is approaching; that is the date on which national quotas expire completely and Britain

loses its special privilege of easy entry for ever. Stiddenly people have taken a look at the waiting ist which is accumulating in the State Department files in Washington and have discovered that the category of so-called "third preference" immigrants (processional, as distinct from technically skilled) is filled for the next three years. And there are few, if any. British, German, Irish or Scandinavian names among the 48,000 on the list.

Mr William Douglas of Careers Incorporated thinks that the new restrictions could put such recruiters for American industry as himself out of business. Dr F. E. Jones of the Working Group on Migration prefers to wait and see. So does the consular section of the American Embassy in London. The law, like env other, has its loopholes. It is certainly possible to go to work in America without getting an immigrant visa: there are various forms of permits allowing for exchanges, training programmes and special exceptions in the national interest. At this point it would be rush to say that American universities or industries could not find a visa for the British apple of their eye. What it is safe to promise, however, is that idle daydreams of "perhaps I'll emigrate" will have to stop. Profes sional men will have to take a firm decision well in advance to go to America or sit back and wait for the exceptional job offer from the company that is willing and able (no one is sure if and how this will be done) to pull strings to get round the new law.

As it stands, the Immigration Act allows 17.000 visas a year for emigrants in the professional class from the eastern hemisphere. (Canadians and Latin Americans are allowed in more freely.) Visas will be awarded on a first-come, first-served basis, with members of each preference class competing with equality for the limited number of places, regardless of their courtry of origin. The actual numbers of professionals taken may be smaller still, as wives and children will be given visas from this list. There is, moreover, a ceiling of 20,000 on emigration of all kinds, other than

relatives, from any one country.

The American Embassy's advice to any intending British emigrants is to apply before the end of next June. After that, really desperate measures might be necessary: emigrating to Canada first, or marrying an American. Helping Britain to stem its brain drain was the last thing Congress had in mind when it tackled this controversial problem in 1965. Yet Bithought might be consolation to any Britons who are unable to move across the Atlantic in the next few years. They might also be glad to be relieved of the Anglo-Saxon's guilt of lolling in and out of American will while countless southern Europeans and Orientals waited outside in vain.

Conceivably Congress could amend the law. Some American companies—those along Route 128 near Boston, for example—are worried about losing their British recruits. And some congressmen are worried about the unexpectedly weak demands for visas in the close-relative categories. The House of Representatives Judiciary Committee may soon hold hearings about the problem. But if any amendment very to be made, priority would probably be given to stomming the drain from underdeveloped countries and attempt then to bend the law to allow more British in would smack of the old favouritism, quite apart from the outcry it would start in this country.

Nuclear Merger

In contrast with the United States and West Germany, Britain has not been a successful exporter of nuclear instruments and equipment. The Parliamentary Select Committee on Science and Technology has explained the poor export performance of British nucleonic firms by the fact that most of them were small, and centred scientifically as well as geographically about Atomic Energy Authority establishments, so that some of them have no customers apart from the authority, and many have no research departments.

The recent merger of three of the largest nucleonics firms, Nuclear Enterprises (GB), and the nucleonics subsidiaries of EMI and Elliott-Automation, so as to create a £2m company, is an important event for the industry. The Industrial Reorganization Corporation supplied Nuclear Enterprises with £600,000 for the take over, all the more willingly, no doubt, because Elliott-Automation had been negotiating the sale of its subsidiary with the American company, Teledyne. The factories of the enlarged Nuclear Enterprises will be at Edinburgh and near Aldermaston, the EMI staff moving from their present sites at Hayes and Wells.

Nuclear Enterprises itself concentrated on the manufacture of instruments such as radiation detectors, gamma-ray cameras, and automatic radioactive sample changers used in research in hospitals, universities and industry. To this range will now be added the health physics equipment, notably hand and foot monitors, and data processing machinery produced by EMI, as well as the extensive contribution of industrial analytic and gauging equipment from Elliott-Automation. Most important, the new Nuclear Enterprises will be able to offer two British made multi-channel analysers, where it previously only acted as import agent for Italian machines.

It is claimed that the new firm will be the biggest of its kind in Europe, but, as so often in the industry of advanced technology, this only means that the company compares with a medium-sized American firm. Nuclear Chicago, to give an indication of American scale, sells \$23m worth of instruments each year, exporting 20 per cent of its output—more than \$750,000—to Britain alone; the top six British firms have a combined turnover of about three million pounds.

The amalgamation of three of Britain's biggest manufacturers of nucleonics may encourage similar association among some of the other three or four bigger firms and subsidiaries. But if and when the big can be persuaded to become bigger, there will still be the problem of how to encourage export and research activity among the forty or so smaller nucleonic firms within the satrapies of the various AEA establishments.

Trade in Technology

WITHIN the next month or so, the Ministry of Technology is hoping to sign a new technological agreement with the Soviet Union. Mr Anthony Wedgwood Benn, the minister, is particularly keen about the agreement. "It will pave the way for closer contact between Britain and the Soviet Union in the future. Each has a great deal to gain from an exchange of information in the fields of forward research, industrial technology and

planning techniques." But Mr Benn thinks that the greatest gains will come from the development of international systems for the exchange of scientific and technological information by means of a world information retrieval and dissemination system.

Similar agreements have already been signed by the United Kingdom with Poland and Hungary and, if they are anything to go by, the Anglo-Soviet agreement is likely to be a pretty innocuous document. But this need not matter very much. The first reaction from industrialists was that with agreements of this sort, what they say is often less important than the cordial relations they foster. The Confederation of British Industry is enthusiastic about the agreement. "The important thing is not the pious statements of intent, but the fact that there is a determination to make the agreements work," one CBI official said. The CBI sent a mission to the Soviet Union recently, and has been surprised how quickly the benefits have been showing themselves. It has also been surprised at the wide range of projects on which the Russians were eager to collaborate—instead of searching around for points of contact, the mission found it was easier to add up the number of things in which the Russians were not interested. Eight particular areas of interest emerged from the CBI mission-electricity supply and generation, heavy generating plant, the motor industry, the metallurgical industry, industrial pollution, patents, the railway system with particular emphasis on containers, and standards. Some of these subjects may be mentioned in the agreement when it is signed; other possible subjects are coal mining machinery, computers and electronics, and chemicals and chemical plants. It is also thought that the Russians may be interested in civil aviation technology. This is a field where Russian designs would be unlikely to sell on a world market, even if there were no political barriers. For one thing, the period between engine overhauls in Russian civil aircraft has tended to be much too short for airline economics.

Some of the bigger British firms already have a foot in the door. Imperial Chemical Industries, for instance, has negotiated its own agreement with Russia, after Sir Paul Chambers met Mr A. Kosygin in 1964. The agreement, signed in October 1966, provides for collaboration in plastics, petrochemicals and synthetic fibres. And British Motor Holdings, while admitting that the new agreement would "obviously be very useful", says that it has already submitted plans for a complete car plant to build two BMC models, the 1100 and 1800, in the Soviet Union. A team of BMC engineers will be going to Russia next month to hold discussions, principally about engines, automatic transmissions and suspension systems. Leyland and Courtaulds are two other British companies which have shown interest in the Russian market, and Leyland has put forward plans for a complete factory to build commercial vehicles in Russia. English Electric has sold a number of computers to Eastern Europe, most recently a System 4 computer to Russia.

But what of Mr Benn's ambitious schemes for an international data storage and retrieval system? So far the Soviet Union has shown interest in only one such proposal, put forward by the Internationa Atomic Energy Agency. This is a development of the scheme now in operation for sharing nuclear cross sections internationally, and would provide an internationally.

national nuclear information service based on Vienna. The proposal has been widely discussed over the past few years, but has not yet been finally agreed. The Soviet Union does have its own information retrieval system, called Viniti, and has done some fundamental studies of language and mechanization. But it is not clear exactly what stage the Russian system has reached. Mr John Grey, of the British Office of Scientific and Technical Information, says that to produce an effective international system it would be necessary to produce standard formats and procedures, as well as compatible indexing systems and programmes. With the third generation of computers, he hopes that this will be very much easier, but he stresses that all systems are still experimental and that the next two or three years are likely to be of crucial international collaboration. "There can't be too much discussion on it," he said.

Culham Divided

It now seems probable that the Science Research Council will be taking over responsibility for at least part of Culham Laboratory. Dr Robert Wilson, who is director of the group at Culham working on astrophysics, says that "agreement has been reached in principle" for the phased take-over of his group by the SRC. But he emphasizes that consultations are by no means complete, and there are a number of questions connected with the staff which still have to be settled. If the transfer can be made, it will do something to restore optimism at Culham—since the Minister of Technology, Mr Anthony Wedgwood Benn, announced in July the decision to cut the laboratory's expenditure by 10 per cent a year for five years, there has been something of an air of gloom. Because the astrophysical work was supported from the fusion budget, it was as vulnerable as any other project at the laboratory.

If the discussions go well, the astrophysical group will be converted to an SRC unit based at Culham. This process should be complete by April 1969, and the group will remain at Culham at least until 1971. The group consists of 18 professionals and 10 others, and the annual budget has been running at something like £0.25 million a year. (This is not a hard and fast figure, because it includes overheads and some laboratory plasma work which the SRC may not take over. The exact financial commitment of the SRC will not be clear until the negotiations are complete.) As well as studying the solar spectrum with stabilized Skylark cockets, the group has been responsible for the measurement of new spectral lines and of atomic cross-sections. t now hopes to move on to stellar spectroscopy, with rockets stabilized on stars.

So far, nothing has been decided about the team which is working on the design of a large astronomical elescope for ESRO. This is a different team, consisting of 25–30 professionals working part time. As yet, the lecision is not urgent, because ESRO has not decided whether to proceed with the project. If the LAS project does proceed, Dr Wilson says, the position of he team working on the design will have to be conidered.

There is little doubt that the move to the SRC will nake for better co-ordination of the British space esearch programme, but there is no particular reason to believe that money will then be easier to come by. The programme will have to find its own level within the competitive atmosphere of the SRC. As a number of commentators—Nature among them—have suggested, a move to the SRC might be the answer for the whole of the Culham establishment. But there has so far been no hint of that.

Facing the Future with SI

A conference of editors of British scientific journals adopted on December 11 a recommendation that editors should collectively encourage the use in scientific journals of the system of metric units known as SI (which is an abbreviation for Système International d'Unités). A document prepared during the past six months by a working party under Professor James Lighthill has produced a detailed list of definitions and suggestions including, in particular, the view that "the journals devoted to science and engineering should seize the opportunity of playing a crucial role in helping to end the confusion and wastefulness (both mental and material) resulting from the present multiplicity of units". This decision has been given the encouragement and the blessing of the Ministry of Technology, which is now hoping for more or less complete metrification of the British system of weights and measures by the mid-seventies.

The basic units of the SI system are the metre (m), kilogramme (kg), second (s), ampere (A), degree Kelvin (°K) and candela (cd). Allowable derivatives include the Joule (J) but not the calorie, the weber (Wb) but not the Gauss, the hertz (Hz) but not the cycle per second and the degree Celsius (°C) but not the degree Centigrade (which is said to be one of the points on which French delegates to the international conferences have placed a great deal of emphasis). One of the characteristics of the SI system is that fractions and multiples of units should wherever possible be quoted to the nearest integral or fractional multiple of a thousand, which means that the Angstrom (10-10 m) is banned and even the centimetre (10-2) is frowned Needless to say, the foot, the pound, the gallon and the Btu have nothing said in their defence.

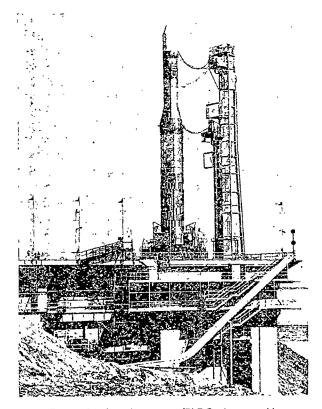

By all accounts, a great many British journals have already agreed to regard 1968 as a period of experiment and of transition. Although the document produced by the working party (see *Nature* next week for further details) seems to have obtained a sympathetic reception, it remains to be seen how many journals will follow Professor Lighthill's suggestion that they should, after a suitable warning period, automatically return manuscripts in units other than SI.

ELDO Fails Again

from Angela Croome

Although the political crises for co-operative European space enterprises took place in 1966, the technological failures which give a gloss of justification to the political wrangling have occurred this year. There were the pre-launch troubles with the first ESRO (European Space Research Organization) satellite in the spring which have made necessary a year's postponement in the launching of the backup vehicle and considerable extra cost. Now the two ELDO shots of the

year, designated Flight 6/1 and 6/2, have both failed. The second of these flight tests from Woomera took place last week on December 5. ELDO, the European Launcher Development Organization, is concerned with space tools and not research. The two launches were stages in the development of a large carrier rocket based on the British Blue Streak for European purposes.

Europa I in launch position (ELDO photograph)

The failure of the second launch has marked similarities with that of F6/1 on September 2. In both cases the programme sequencer was implicated. This is mounted on the French second stage and both its manufacture and its checkout are French responsibilities. The cause of last week's vehicle failure was very simple: the programme-sequencer did not start at take-off and did not work at all during the few minutes' flight. Consequently the second stage (Coralie) did not separate and because it did not separate it did not fire. The second stage electronics failure on September's F6/1 test was more complex. Then the sequencer malfunctioned briefly—possibly for as short a time as 200 milliseconds—during the first/second stage separation phase as Blue Streak boost ended. The consequence was that although the second stage separated it did not fire and a few seconds later was automatically destroyed. On both the F6 flights the Blue Streak booster stage functioned "normally", as it has done on the preceding five flight tests.

Apart from giving the first "live" test to the second stage, the objective of F6/2 was an operational run of the complete ground network for control and tracking. This was partially achieved. The upper parts of both this year's flight vehicles, representing the German

third stage and the Italian test satellite, were dummie though of correct weight and aerodynamic characteristics. Despite the setbacks with the second stage there is apparently to be no change in the firing schedul for which 12 flight tests of the Europa I configuration extending through to 1970 are laid down. The nex flight (F7), due next summer, will have all three rocke stages live and will be the first potential orbital flighthough not carrying a fully instrumented satellite Clearly the French will have to do some intensive homework to avoid frustrating this trial and it successors. The F6 booster has already completed it tethered test firings at Spadeadam (Cumberland) and is being made ready for shipment from Hawker Sidde ley's Hatfield works.

The still distant F11 and F12 orbital tests may carr components of the perigee/apogee system (PAS)—th key element in converting Europa I into Europa IIor a low polar orbit into the high equatorial typ favoured for communications satellites. France head the list of intending buyers of the Europa II launche on which she is dependent for her ambitious plans o direct French communications to link metropolitax France with French-speaking territories oversea (SAFRAN and SAROS). Enhanced reality was giverto the PAS project last week by the formation oan industrial management company representing th 11 European companies involved in its developmen-Called SETIS (for Société Européenn for ELDO. pour l'Etude et l'Intégration des Systèmes Spaciaux with a full-time technical staff drawn from these firms a French president and a Paris headquarters, its chie task will be the coordination and integration of work on PAS. The firms involved are: Hawker Siddeley Rolls Royce (Britain); SEREB (France); Bölkow Erno (Germany); C.I.A. (Italy); A.C.E.C., M.B.L.E and B.T.M.C. (Belgium); Philips and Fokker o Holland.

No Joy for Euratom

EURATOM struggles from crisis to crisis. The lates misfortune to assail the organization is a drastic budge cut, enforced last Friday at the Council of Ministers in Brussels. Although the Euratom commission has proposed a budget of \$82 million, the ministers cut this down to \$40.695 million after discussions which lasted all day. Even the commission's proposal was modest in comparison with earlier years, when the budget has run at about \$90 million.

The budget cuts are only the visible symptoms of ε malaise which now threatens the whole future of the organization. As is reported elsewhere in this issue, the Dragon reactor project, by general agreement a success ful example of co-operation, is threatened by the in ability of Euratom to determine its research programme for 1968. This kind of project, in which Euraton contributes but is not wholly in control, seems to have been a main topic for argument when the ministers men last Friday. All that could be agreed was that these projects would be further considered in the next fewmonths, but no provision was made for them for 1968 At the meeting, France and Italy were both attempting to cut back the budget, while West Germany and Holland supported the commission and Belgium and Luxembourg remained neutral. With the refusal to sanction work on association projects, the only work

that can go ahead in 1968 is the work in Euratom's own laboratories.

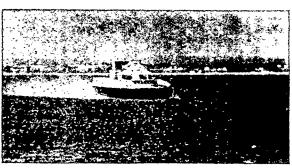

The French view of the association contracts is that, if the work is worth doing, the money will eventually be forthcoming, but that the contracts must be left in suspension until the new arrangements for co-operation can be worked out. The French argue that it is no longer sensible to produce a grand plan detailing all that needs to be done; instead, each individual decision should be agreed by the Euratom members. This formula, the argument goes, need not be applied rigidly, and if any member of Euratom wanted to opt out of any particular project it could do so, leaving five, four or even three countries collaborating. With this as a basis, it would be impossible for any single country to veto a project which the others wanted to support.

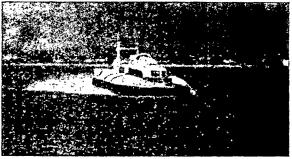

Developing Hovercraft

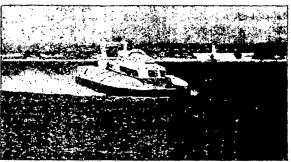

WHEN the first hovercraft flew nearly nine years ago, it did so without the aid of flexible skirts. The air cushion beneath the craft was kept in place by jets of air around the periphery, which produced a hover height of ten inches. But, as Mr W. C. Crago, Chief Research Engineer for the British Hovercraft Corporation, explained to the Institution of Mechanical Engineers on December 12, this was an unsatisfactory solution. It used far too much power, so much that, without enormous power units, hovercraft designed then would have had a clearance of only about 1 ft., not enough to clear even quite small obstacles. The solution was the invention of the flexible skirt—which offered increases in hard structure clearance by as much as eight times. But the arrival of skirts brought further development problems, and these formed the substance of Mr Crago's talk.

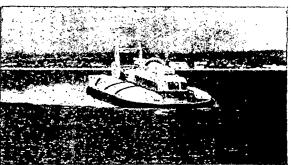

The modern hovercraft skirt, Mr Crago explained, is a sophisticated inflated structure, consisting of an upper bag portion which is more or less self supporting and acts as a shock absorber in heavy waves—and a series of discrete fingers which hang from it. One of the critical parameters is the pressure inside the skirt. There are two opposing demands—to form a stable structure, skirt pressure should be high, but, to minimize drag and improve hover performance, a low skirt pressure is better-and a compromise, based on model testing, is usually adopted. Hovercraft also demonstrate a form of behaviour known as "plough-in", for which there is no real counterpart in other marine craft. The pictures show this process happening to an SRN 6 hovercraft during trials. As can be seen, the process is started by the contact of the skirt with the water; the drag then causes the nose to dip even further, and if unchecked the process can lead to overturning of the craft. Fortunately, the process is well understood, and Mr Crago said that skirts of low hydrodynamic drag should be used; for this reason, skirts with fingers are particularly suitable. Another possibility under active investigation is the lubrication of the skirts by air, which is blown down the outside of the skirt and reduces drag at the point where the skirt comes into contact with the water. This seems likely to be a very useful development.

As well as the danger of overturning at high speed after plough-in, low speed overturning can sometimes be experienced. This happens at a fixed forward speed, when the length of the wave generated by the air cushion is the same as the length of the craft. Again cushion pressure is an important criterion. Finally, Mr Crago discussed the problem of skirt wear. One of the problems in investigating wear, he said, was that it was difficult to reproduce in the laboratory the type of

An SRN 6 hovercraft "ploughing in". Photograph by permission of the Institution of Mechanical Engineers.

wear—delamination—shown by the cushions in operation. Ultimately it was found that a specimen mounted in the outlet of an air blower could be made to flap like a flag, and produce delamination of the material much like that observed in practice. As a result the skirts, which consist of a nylon or terylene core coated on both sides with rubber material, have been markedly improved.

Commonwealth Foundation

THE Commonwealth Foundation has produced its first progress report after 18 months of official activity as a charitable organization providing funds for professional bodies on a supra-national basis. The Foundation aims to encourage and support contacts and exchanges between members of the professions in the Commonwealth countries, through conferences, exchanges of personnel and information, and the setting up of Commonwealth-wide associations not centred on Britain. So far grants for nearly £200,000 have been allocated for sixty different projects throughout the Commonwealth. Accountancy, architecture, education, engineering, law and various aspects of medicine and science have been supported, with amounts varying from £35 for publishing an accountancy bulletin in Zambia, to £24,000 for professional centres with basic reference libraries in Kampala and Port of Spain.

A meeting of representatives of the professions, arranged by the British Commonwealth Office in 1964, produced the idea for the Foundation. The proposal was announced at the Commonwealth Prime Ministers' Conference in June 1964; terms of reference were agreed in 1965 and, after appointment of a permanent staff of three, the Foundation became operational in March 1966. Twenty-four of the twenty-five Commonwealth countries contribute a quarter of a million pounds a year to the Foundation, at rates agreed to by the Prime Ministers concerned, to correspond with the size and affluence of each country.

Each contributing country is represented on the Board of Trustees, which has so far met five times, under the chairmanship of Sir Macfarlane Burnet. Applications for grants are accepted from individuals or professional bodies throughout the Commonwealth, for first consideration by the full-time director, Mr John Chadwick. Provided the applicant can produce good reasons for his application, and it falls within the terms of reference of the Foundation, it is passed to the Board of Trustees with the director's report. Chadwick thinks the board will have to meet three times a year at least, and a sub-committee has been set up to consider applications which are urgent or for small sums of money. The main task of the staff in getting the Foundation has been to make its existence known, for individuals and professional bodies can only apply for grants if they know the facilities exist.

The Foundation, which describes its private but international set-up as "without precedent", is not stating its policy too firmly at this stage, and is prepared to experiment. A pilot project is under way in the field of journal distribution. The London Bureau of Hygiene and Tropical Diseases is collaborating with the Foundation to provide copies of the *Tropical Diseases Bulletin* for those in underdeveloped countries who cannot afford the subscription. The London bureau is pleased how quickly the Foundation accepted the scheme.

Dragon Reprieved

THE Dragon high temperature reactor project will be kept in being for one more year at least. During 1968, the costs of the project will be borne by the United Kingdom, Austria, Denmark, Norway, Sweden and Switzerland. The Euratom countries, the other supporters of the project, still have no firm policy for

1968 and thereafter. As a result, they have so far refused to extend the project until 1970. But they have at least been able to sanction an arrangement by which Austria, Denmark, Norway, Sweden and Switzerland pay their normal contributions to the 1968 budget of £2·1 million, with Britain making up the rest. It has also been agreed that Euratom will finally make up its mind by the end of July 1968 and, if approval to continue the project is reached, then the contributions made for 1968 will be taken into account. But if no agreement is reached, Euratom will waive its rights to the written down value of the fixed assets of the project. Meanwhile, Euratom will continue to receive the same benefits, in the form of information and secondment of personnel to the project, as if it were paying its full share.

This generous settlement indicates a good measure of enthusiasm for the project among the non-Euratom countries. Some observers see the high temperature reactors as a good possibility for industrial use, able to produce electricity and high grade steam in reactor sizes smaller than would be economical with other reactor types. The news of progress with Dragon comes at the same time as the first experimental results from another high temperature reactor, the AVR, built in Julich by Brown Boveri/Krupp Reactorbau GmbH for a group of German utilities. The reactor has so far run for about three months, most of the time well below its full design capability of about 50 MW (thermal). The work has established that the system is safe, and approval has been given for full power operation. Powers of 18 MW (th) and helium outlet temperatures of 590° C have been reached.

Living at High Altitude

Some 30 million people throughout the world live above 10,000 feet—more than the total population of 85 per cent of individual nations. They live under perpetual physiological stress, that of hypoxia—oxygen shortage—often compounded by cold stress. Yet there is little systematic knowledge of the effect these conditions have on the high-altitude dwellers and the biological adaptations that are developed to cope—a situation thrown into relief by next year's Olympic Games in Mexico City, which lies at 7,349 feet.

To counter this lack and promote useful research programmes the regional office of the World Health Organization and the US International Biological Programme Committee jointly sponsored an international conference on "Man at High Altitude" in Washington last month. The study of high altitude peoples is of great interest to the Human Adaptability Section of IBP. The conference hardly threw a glance at the problems of Olympic athletes, but a couple of papers were relevant to this practical problem as they discussed the relation of oxygen uptake and work capacity.

Dr R. F. Grover of the University of Colorado has compared lung function and working capacity on athletes from two groups; one, a community settled for several generations at Leadville 2 miles up in the Rockies, the other a group from lowland Kentucky It was found that maximum capacity for consuming oxygen at Leadville was reduced as much in the Leadville native athlete as in the Kentucky athlete Dr Grover wondered whether the long-adapted Andeas

native (Peruvians have lived at about 10,000 ft. for thousands of years) would be physically superior (at altitude) to the well conditioned athlete from the lowlands. Among Leadville non-athletes, hypoventilation (shallow breathing) was common.

This seems a regular characteristic of those highland communities which have been most thoroughly studied. Dr John W. Severinghaus of the University of California San Francisco Medical Center described work on Peruvian Indians which indicated that the native who has always lived at high altitude does not breathe more deeply in a diminished oxygen atmosphere whereas a sea-level native who goes to the highlands does. Dr Severinghaus suggests that the highlander has lost sensitivity in the chemo-receptors governing this reflex. This may have very far-reaching consequences: longevity, intelligence, learning, fertility, infant survival, susceptibility to respiratory diseases may all be implicated. This reflex loss appears to tie in with the characteristic health hazard of high altitude, pulmonary oedema. This was by far the most common affliction of the several thousand Indian troops who have been stationed on the Himalayan border between 11,000 and 18,000 ft. since the 1962 emergency. Dr Inder Singh, in discussing the clinical problems encountered by the Indian forces medical services in the area, reported that diuresis induced by drugs has been found to relieve the condition.

A number of recommendations for both research projects and for practical action were adopted by the meeting. One was the preparation of a short, concise book on high altitude medicine to cover high altitude diseases, modification of common sea-level diseases at high altitude, as well as the modification of drug and anaesthetics action. It was also agreed to found a research centre of high altitude studies to act as a clearing house for information on the subject and improve scientific communication in this field.

Manpower for Electronics

A CONTINUING shortage of scientific and technological manpower is envisaged in the electronics industry, together with a growing demand for engineering skills. These and other findings of the enquiry undertaken by the Manpower Research Unit, in association with the Electronics Economic Development Committee, are presented in *Electronics*—the fifth in a series of reports by the Manpower Research Unit (HMSO, 6s. 3d.). The purpose of the enquiry was to gain a clearer picture of likely manpower developments within the industry up to and beyond 1970, and forty-six firms participated.

According to estimates made by the Ministry of Labour, 371,000 people were employed in the electronics industry in June 1965—288,000 were in electronics and 83,000 were in telecommunications. Shortages of labour were common throughout the industry. The over-riding factor in determining the size of the labour force—not surprisingly, perhaps—was the level of demand for products. The development of microcircuits, the report says, calls for more support at technician level, while the development of printed circuits and semi-conductors would probably involve less mechanical assembly and a move from male to female assessors.

Most firms, it is reported, thought that technological

change, including the use of computers for planning and managerial control, would be the principal means of increasing productivity. Incentive schemes were favoured by some firms but criticized by others and other important contributions to productivity were expected from work and methods study, training and standardization of production.

Estimates were made of changes in the occupational structure of the industry between 1965 and 1970 and an increase in the employment of scientists and technicians is expected in the fields of radio and other electronic apparatus and in telecommunications. Shortage of production engineers, systems and circuit engineers and computer staff was particularly evident at the time of the enquiry, and it was suggested that, although in general the basic cause of shortages was the rapid expansion of the industry and the rate of technical change within the individual firm, the most important fact was the continuing transfer of scientists and technologists to managerial posts. Furthermore, the report suggests that there is a need to encourage more young people to take up science and engineering and the "one-way traffic" of graduates into the academic field is criticized.

Parliament in Britain

Nuclear Ships

MR A. Wedgwood Benn, Minister of Technology, has agreed to consider the recommendation of the Select Committee on Science and Technology that a departmental committee be convened to examine the possibilities of nuclear marine propulsion. He pointed out that the responsibility for the Atomic Energy Authority, the nuclear industry, the manufacture of marine engines and shipbuilding had all been placed on his department. It was in touch with all the interests concerned and he intended to re-examine the position to ensure, as far as possible, that Britain was in a position to embark on a major project as soon as it appeared that commercial demand for such ships justified the considerable cost involved. (Written answer, December 5.)

Patents

In a debate in the House of Commons on November 30, Mr C. Fletcher-Cooke and Sir Lionel Heald challenged the idea that the Patent Office and the Trade Mark Registry should be self-supporting. Mr Fletcher-Cooke maintained that Parliament had never said that they should pay their way and argued that the increase in fees proposed for filing patent applications, complete specifications, trade marks and their renewals was unjustified and constituted a discouragement to invention. Sir Lionel Heald questioned the organization and efficiency of the Patent Office. Had any real effort been made to produce a more modern and efficient system? The Minister of State at the Board of Trade, Mr G. Darling, who replied for the Government, did not think that the increased fees would discourage applications, and pointed out that on an average the Patent Office spent £55 on each application against the £15 which would now be received and that 70 per cent of all applications came from overseas. He paid tribute to the efficiency of the Patent Office and its staff. He would be glad, he said, to see it moved from its present premises, but he did not think it should be run at a loss. (Debate, November 30.)

NEWS AND VIEWS

What Price Uniformity?

THE decision by the conference of editors which the Royal Society has sponsored (see page 1061) that British journals should quickly persuade their contributors to adopt the SI system of units is a reasonable step, on the face of things at least. There is a good deal in the argument that life would be simpler, and possibly a good deal simpler, if all scientists used more or less the same system of units. It goes without saying, of course, that scientists, who do most to create new units of measurement, are less hampered than most other kinds of people-architects, for example-by the coexistence of different systems of units, but even in science it is sometimes hard to tell where inconvenience stops and confusion begins. It is also, perhaps, quite proper openly to acknowledge that the devoted people who seek uniformity are also often much addicted to the invention of new units. The passion for uniformity has, for example, produced as one of its side-effects the strange confusion which now abounds about the units of magnetic flux. There may be quite unexpected benefits if the energies of the unit-mongers can now all be harnessed to a single and probably a lasting cause. Whether, in these circumstances, it is reasonable for by-standers to hope that metrification of the scientific journals will somehow help the rest of the world to abandon its devotion to the inch and even centimetre is another matter. Mr Wedgwood Benn may be determined to show that in weights and measures, if not in monetary systems, Britain is capable of satisfying the most exacting demands of the President of France, but the Ministry of Technology must know by now that its real battles will come with the butchers, bakers and candlestickmakers, not with laboratory scientists.

That said, it remains to be seen how quickly the SI system will sweep everything in front of it. In matters like this, editors of journals may be influential but their influence cannot be decisive. In the last resort, there are limits to the extent to which contributors can be made to toe a common line. The problem is not merely that quantities such as 1.3 Å must be replaced by 130 pm (for picometre). Sometimes there are no exact equivalents for the units which authors choose to use. Who but an author can translate 1,500 feet,for example? In the circumstances, the journals can only provide encouragement and, sometimes, discouragement. Most of them, no doubt, will be guided not so much by the convenience of contributors as by that of readers—this at least is how the balance should be struck. This is where consistency is a real asset, and where it will also be extremely helpful if the practices of all the journals can be brought more closely into concert. But flexibility also matters, which implies

that authors should not shrink from lapsing even into e.g.s. units if this seems to serve the convenience of readers. Familiarity is also important, which means that those who have spent lifetimes using words such as Ångstrom and calorie should be allowed a generous interval in which to change their ways.

The question then arises of how Nature will respond to the call for a uniform adoption of SI units. The first thing to be said is that the problems of an international journal are in many ways exceptional, and at present there is only a hope that journals in the United States will follow the British. The scope of this journal is also a complication. It may not be entirely unkind to biologists to suggest, for example, that some of them may not know what a Joule is, let alone how to use it instead of a calorie. In the circumstances, it would seem that the best course will be to use 1968 as a year of experiment biased in favour of SI units, and there are a number of ways in which this can be done. One way in which this can be done is to allow SI units to be abbreviated but to require that others should be spelled out in full. Thus an author will be allowed to say Hz, but abbreviations such as c/s and c.p.s. will be replaced by "cycles per second". The dyne (which is 10-5 Newtons) will be spelled out in full. For the time being, the atmosphere will remain the atmosphere, instead of being converted to 101-325 Newtons per square metre. But it is clear that the British thermal unit, beloved of engineers, is on the way outin the new system, it works out at 1055.06 Joules. And if people insist on using the nautical mile, a unit wholly contrary to the spirit of the SI system, it is hard to see how they can be out-manoeuvred, because the nautical mile is wellnigh unconvertible. In fact, it is equal to 1.85318 km, on the European side of the Atlantic at least. To start with, at the beginning of 1968, there will be nothing to be done about "1,000 feet" but to complain. It will also seem entirely sensible that units such as the Angstrom, centimetre and gram should be allowed to flourish (if authors wish) without much hindrance for the time being. For the rest, it will be interesting to see what happens. This is not a crucial issue, but SI deservesa fair wind.

Count More Galaxies

Some of the first results of the new sky survey carried out at the Mullard Radio-astronomy Observatory at Cambridge were described last week to the Roya. Astronomical Society by Sir Martin Ryle. From hispreliminary paper with Mr G. G. Pooley, it seems that the Fifth Cambridge Catalogue of radio sources with

contain something like 100,000 sources per steradian, compared with 600 per steradian for the fourth catalogue and a mere 45 for the third, which was based on measurements made in 1958. One of the most striking of the points made by Sir Martin Ryle last week was that the region of the universe now accessible to the instruments at Cambridge is so great that the outer limits of observation probably correspond to times in the history of an evolving universe at which the formation of galaxies was commonplace.

The instrument being used in the new survey is the one mile telescope. A large tracking array 5,000 feet by 60 feet is used in conjunction with movable instruments in such a way that the combination of the records of successive scans of the same part of the sky can simulate the sensitivity of a much larger telescope. In the parts of the survey so far carried out, the aerial system has been used to track chosen parts of the sky for 12 hours a day in a period of 2 months. The result, at a frequency of 408 MHz, is a survey of a patch of sky 4 degrees in diameter. So far, three such patches have been covered with a limit of sensitivity of 0.01×10^{-26} watts m⁻² sec⁻¹. With plausible assumptions about the intensity distribution of the radio frequencies, this corresponds to a limiting flux density twice as great as at the frequency of 178 MHz used in earlier surveys. Each of the three patches of sky so far surveyed appears to include some 200 radio

One of the principal objectives of the work so far has been to determine the variation of the numbers of sources with varying brightness. In practice, this means constructing the relationship between log N and $\log S$ where S indicates radio flux and N the number of sources with radio flux greater than S. It has been necessary to make comparatively rapid surveys of the whole sky so as to pick out comparatively intense radio sources which can be used as a means of calibrating the new survey. Sir Martin Ryle said last week that the initial slope of the curve—corresponding to comparatively intense sources—is essentially the same as the value of -1.8 obtained in earlier surveys, but that the slope progressively decreases in magnitude to about -0.8. Compared with the predictions of a static Euclidean model of the universe with uniformly distributed radio sources, the new survey shows an excess of sources of intermediate radio flux. Sir Martin Ryle said that the differences between observation and the predictions of an Einstein-de Sitter model and of the steady-state theory are considerable, and great enough to show "that important evolutionary effects are taking place". He explained that "The observations show a distribution in which there is an apparent ncrease in the space density of sources followed by a narked decrease. The gradient of the decrease may pe determined by the spread in intrinsic luminosities and, if this is as great as that found for the intense ources, the cut-off must be very rapid." This cut-off probably corresponds to the "epoch of galaxy ormation".

Binocular Vision in Cats

from our Neurophysiology Correspondent ULESZ has recently shown that depth perception in uman vision does not depend on the existence of monocular cues but that it can be based simply on disparities between the two retinal images (see Nature, 215, 1225; 1967). Barlow, Blakemore and Pettigrew (J. Physiol., 193, 327; 1967) have now set out to discover the mechanisms involved in depth perception in anaesthetized cats. The nub of their conclusion is that in cats, as in men, the recognition of structure usually precedes the investigation of depth but that this sequence of events is not essential.

The technique is to record from single cells in the primary visual cortex, stimulating them either with moving black and white bars or with the edges between black and white areas. Having found the gross receptive field for a single cell, the receptive field is determined for each retina separately. The next step is to determine the disparity between the responses to two identical stimuli, presented binocularly, which produce the greatest excitation of the cortical unit.

For each cat they found a range of disparity of about 6° in the horizontal plane and 2° in the vertical. This is interesting, because it is similar to Julesz's result. He found that man could maintain fusion of a stereoscopic pair of images as they were pulled apart on the retinae for a distance in the horizontal three times greater than that in the vertical direction. Precise measurements of retinal disparity are extremely difficult, even in an anaesthetized preparation, because of residual eye movements, and the impossibility of determining the direction of each optic axis accurately. Barlow et al., however, reduced possible movements by paralysing the preparation with 'Flaxedil' and attaching the two eyes to firmly fixed rings. Ophthalmoscopic observation during the experiments showed no perceptible changes in eye position. In any case, the most important feature of their results is the range of disparities observed for each cat, coupled with the horizontal-vertical anisotropy. They suggest that their results indicate that the cat observes depth over a wide range, but at low accuracy (because of poor depth of focus in the visual field), unlike man, who perceives depth accurately over a short range. This seems rather unlikely, both on behavioural grounds and because there would seem to be little advantage in seeing depth in out-of-focus objects. Their results could equally well be taken to show that cats, like humans, can accommodate a large range of depths, or retinal disparities at the same distance and that each part of this range is served by a particular population of cortical neurones. It would be interesting to know whether cats could recognize structures in Julesz patterns: in other words, it would be interesting to know whether cats need to recognize structure monocularly before they can determine the retinal disparities leading to depth percepts. At the moment there is no evidence against this, although Barlow and his colleagues say that their results suggest that the cat recognizes primitive structure first and then decides on the appropriate pairing of parts from the fields of vision of the two eyes.

One of the most important by-products of these experiments is the renewed emphasis on the need for very precise control of eye movements, refractive correction and stimulus presentation in studies on the visual system. Indeed, this is one of the few reports in this field where adequate care has obviously been taken.

No Easy Cure for Migraine

from a Correspondent

"I have my own remedy," said Sir George Godber, in his address to the second Migraine Symposium, held at the National Hospital, Queen Square, on November 24. With this remark, Sir George, who is chief medical officer at the Ministry of Health, associated himself with the many migraine sufferers who have learnt to manage their headaches and the associated symptoms after years of trial and error. For them and for others whose migraine is still unmanageable, the second symposium was a sort of progress report on current research and therapy. Patients who are treated with mono amine oxidase inhibitors and who include certain foods—particularly chocolate and cheese—in their diet tend to suffer from headache and hypertension; the similarity to the dietary factors in migraine was noted. Certain amines, in particular tyramine and dopamine, have been implicated as the causal agents when they are contained in the diet, and gain access to the general circulation. It has now been demonstrated that 100 mg of tyramine taken orally will induce migraine in patients with a convincing dietary history, and who normally exclude foods containing these amines from their diet. On the other hand, there does not appear to be any deficiency of mono amine oxidase in the temporal artery of migrainous subjects when a small biopsy of this artery is removed in an acute attack and stained histochemically. There is increasing interest in the action of amines on blood vessels in vivo and in vitro, and the relevance of these findings to migraine may be significant.

On the therapeutic side, Sir Derrick Dunlop, Extra Physician to the Queen, and chairman of the Ministry of Health's committee on the safety of drugs, reviewed the current methods of treatment. Ergotamine, either orally, by inhalation, injection or in the form of a suppository, remains the most effective form of treatment in an attack, if it is taken sufficiently early. Methysergide is a useful prophylactic, but when taken in adequate doses may lead to inflammatory fibrosis. There have been reports of the development of retroperitoneal fibrosis, valvular heart disease and pleuropulmonary fibrosis during methysergide therapy. Prompt reduction in the dose of the drug does lead to

regression of the side effects.

The development of newer drugs and the pharmacological investigation of other compounds of ergot was the subject of one of the papers. Of the compounds investigated, at least one, 1-methyl-ergotamine. deserves clinical trials. It is difficult to design such trials and equally difficult to assess the effectiveness of a particular drug or regime in a subjective condition such as a headache. An added difficulty, described in one of the contributions, is that patients often do not take the drugs as prescribed. This is demonstrated by the amount of the drug returned by the patients on their next visit to the doctor. Despite the many pitfalls, clinical trials are obviously essential in establishing the value of any new treatment, and conflicting results may be explained by the nature of the trial or the selection of patients admitted to it. The use of hormones in migraine was the subject of another contribution, which described the trial of a progestagen as a prophylactic in migraine. While results are not vet complete, the initial response is not encouraging.

Viruses and Cancer

A LARGE audience attended a review lecture on virus and cancer, given by Professor J. F. Enders at the Royal Society on December 8. Professor Enders was concerned with the problems of the relationship of the virus to the transformed cell, as illustrated by experiments with the oncogenic agent simian virus 40. He posed two questions. Does the virus persist in transformed cells and, if so, in what state? Does the virus specifically condition the shift from normal to cancerous state? The fact that certain viruses are capable of inducing solid tumours or leukaemias when introduced into a susceptible host under the appropriate conditions has been known since the beginning of the century. As an introduction to his lecture, Professor Enders outlined some of the features of oncogenic viruses; they occur in four of the six classes of animal viruses and, in general, do not seem to differ biologically or biochemically from non-oncogenic viruses. They do, however, have two outstanding features. Referring to oncogenic members of the adeno and papova viruses, he pointed out that they replicate in the nucleus and that the expression of the viral genome is partly suppressed so that production of new particles is stopped short of Attempts to isolate these infectious completion. viruses from tumours which they induce have failed, and this has formed the subject of much investigation. In addition, because they replicate in the nucleus, these viruses can react directly with cellular DNA which, as might be expected, is reflected in unusual changes in the normal functions of both the virus and cell. Professor Enders described how, for simian virus 40, both direct and indirect evidence has been produced to show that the viral genome can be expressed in at least two different ways in the transformed cell. Interesting indirect evidence which has come from immunological procedures has led to the discovery of two new virusassociated antigens in the transformed cell: the S antigen which only occurs in the cell nucleus, and the T or transplantation antigen. Professor Enders and his associates have shown that S antigen can appear in the absence of T antigen in cells which have been exposed to SV40. Whether or not such cells become oncogenic as a result of exposure to the virus has not yet been established.

Professor Enders related how he and his associate: had investigated the phenomenon of tumour progres sion and had shown that, when hamsters are inocu lated intravenously with one million transformed hear cells, oncogenicity increased with animal passage and * striking increase in the rate of growth of tumour was observed. Furthermore, metastases—a sign o high malignancy—were associated with tumours which have been induced by animal passaged cells. It ha been concluded that "oncogenic potential of cells transformed in vitro by SV40 may vary widely and this variation is independent of the presence of the viragenome".

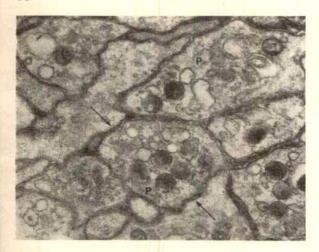

Progress in Thrombosis

from a Correspondent

A conference on thrombosis was held in Washingtoin November to consider the effectiveness of currer trends in investigation and how improvements can b made. The conference was sponsored by a task force

on thrombosis of the Division of Medical Sciences of the National Research Council in association with the International Committee on Haemostasis and Thrombosis, and was attended by more than 150 people from 15 countries.

Dr D. G. Frieman of the Beth Israel Hospital, Boston, working on venous thromboembolic disease, has found the incidence of pulmonary embolism in routine post-mortem examinations to be more than 40 per cent. He has found a high incidence in patients with gastro-intestinal bleeding and a low incidence in patients with cirrhosis. Dr R. E. Horowitz of the University of Southern California School of Medicine confirmed the low rate of clinical diagnosis of pulmonary embolism when this is compared with the autopsy findings. Dr Sevitt of Birmingham described his findings in post-mortem examinations of older injured patients: 65 per cent had deep vein thrombosis of the legs without embolism and 20 per cent of the patients had a major pulmorary embolism. It appeared that bed rest and not the injury was the precipitating factor. Dr E. M. Devitt of Cornell University considered that suppression of lactation increased the incidence of

Part of an aggregate of tightly packed platelets (P) in an "artificial thrombus" produced by Chandler's method. Dense material is seen between adjacent platelet membranes (arrows) after treatment with ruthenium red × 20,000. This dye is thought to stain acid mucopolysaccharides external to cell membranes (Luft, J. H., Fed. Proc., 25, 1773; 1967).

post-partum venous thrombosis. Dr L. Dexter of the Peter Bent Brigham Hospital, Boston, provided valuable data on the prognosis of massive but not immediately fatal pulmonary embolism. Approximately one half of such patients die in half an hour and three-quarters in two hours. The pulmonary circulation has to be reduced by about 50 per cent before circulatory disturbance arises. The alterations in the haemodynamics of the venous system of the lower limb following thrombosis were described by Dr J. A. Haller of the Johns Hopkins Hospital, Baltimore. The clinical outcome may well depend on whether the circumflex femoral veins become occluded.

Speakers on epidemiology of thrombosis attempted to estimate the magnitude of the problems of cerebral thrombosis and acute myocardial infarction. It was concluded that there were few reliable data on cerebral occlusion but that the Framingham heart epidemiological study provided data on coronary disease. Dr F. H. Epstein of Michigan described how the epidemio-

logy of coronary heart disease is complicated by the difficulty of epidemiological studies among the living so long as this is confined to manifest disease rather

than the underlying lesion.

The anatomy of a thrombus was described by Dr Chandler of Georgia, who again emphasized the importance of platelets and leucocytes in the structure of the thrombus, as well as the episodic course of its development. An account was given of the electron microscopic appearance of experimental thrombi by Dr J. E. French of Oxford; platelets in an experimental thrombus are not fused together initially and there is a narrow gap between them. A coating material, possibly mucopolysaccharide, has been

observed on the surface of the platelets.

Dr T. Ashford of Boston described observations on the discontinuous nature of the endothelial cells in special areas. Contraction of endothelial cells may be responsible. Simple relaxation would then be sufficient to reconstitute the surface. The role of fibrin in surrounding platelet aggregates and in preventing their disintegration was described by Dr N. F. Rodman of Chapel Hill. The aggregation of platelets under the influence of adenosine diphosphate has a biphasic pattern; the secondary aggregation can be prevented by the ingestion of aspirin (Dr Sucker, New York). Dr Mustard of Hamilton, Ontario, has demonstrated that, in certain circumstances in vivo, platelet aggregation can be reversed by compounds such as aspirin and phenylbutazone.

Origin of Man

from our Cell Biology Correspondent

Comparison of the structure of protein molecules—chemical palaeogenetics as Zuckerkandl calls it—is clearly going to provide important evidence of genetic and hence evolutionary relationships between different species. Zuckerkandl has already produced a convincing picture of the evolution of the haemoglobin—myoglobin molecule in mammals, and Sarich and Wilson (Science, 158, 1200; 1967) now suggest, on the basis of a comparison of the antigenic properties of serum albumins of the anthropoids, that human beings and African apes shared a common ancestor as recently as five million years ago. Most palaeontologists have inferred from the fragmentary fossil record that this divergence occurred at a considerably earlier point in time.

Earlier this year Sarich and Wilson (Proc. US Nat. Acad. Sci., 58, 142; 1967) found that the serum albumins of man, apes, old and new world monkeys all react to about the same extent with antibody against the albumin of Galago crassicaudatus. (Galago, the bush baby, is a "living fossil"; it is a lemur-like animal with many of the skeletal characteristics of the fossil insectivores from which the primates evolved.) They argued from this that the serum albumins of all the anthropoid lines have changed to about the same extent as they have evolved from the common ancestor. In other words, the albumin molecules in the anthro-

poid lines have evolved at a steady rate.

In their latest experiments they find that human, chimpanzee, gorilla and orang-utan albumins all give virtually identical reactions with antiserum against human albumin. To make these serological tests quantitative, they have measured an index of

dissimilarity, that is the factor by which the concentration of antiserum against a particular species of albumin has to be raised, in complement fixation experiments, to give a reaction with a heterologous albumin equal to that given with the homologous albumin. For example, the index of dissimilarity between human and chimpanzee albumins is 1-14.

The very similar antigenic properties of albumins of humans and African apes imply that these molecules have very similar structures. If Sarich and Wilson's previous conclusion—that albumin molecules of all the anthropoid lines have evolved at steady rates since they diverged from a common ancestor—is accepted, it follows that humans and African apes shared a common ancestor much more recently than is usually supposed.

But how can the index of dissimilarity be related to real time? The fossil record of primate evolution is too fragmentary to make a direct correlation, but Reichlin (1966) and Salthe and Kaplan (1966) have related the index of dissimilarity of various dehydrogenases of fish, amphibians, reptiles and birds with the fossil record which shows when these classes diverged. The logarithm of the index of dissimilarity, measured in immunological experiments, is approximately proportional to the time of divergence. Assuming this relationship holds for the serum albumins of primates, Sarich and Wilson calculate that humans and African apes had a common ancestor only five million years ago. Not every anthropologist who has studied the fossil record would argue against this date, but it will remain tentative until it has been proved that serum albumins evolve at much the same rates as other proteins. Sarich and Wilson suggest that an immunological study of the serum albumins of ungulates, for which there is an extensive fossil record, might settle this point.

Nucleases

from our Molecular Biology Correspondent

One of the most beguiling visions on the horizons of enzymology is the prospect of being able to compare the catalytic mechanisms of a range of endonucleases. The three-dimensional structure of one of these is already largely known, and others are being studied; sequences have been determined, and an enormous mass of enzymology and protein chemistry has accumulated. Some interesting new work on T1 ribonuclease and on staphylococcal nuclease has now been described.

Tl ribonuclease is remarkable because, although it binds to a highly negatively charged substrate, it is nonetheless a very acidic protein, with only five basic groups (three of them histidines). As a first step to defining the active centre, Takahashi, Stein and Moore (J. Biol. Chem., 242, 4682; 1967) have studied the inactivation of T1 ribonuclease by iodoacetate, a reagent which inactivates pancreatic ribonuclease by reacting with the histidine residues at the active centre. It is startling to find that in T1 the reaction occurs at a glutamic acid residue—an amino-acid not previously imagined to be capable of reacting with iodoacetate. The carboxyl group, identified as glu-58, is esterified to —COOCH₂COO-. This involves a displacement of the charge by 4 Å, which is evidently sufficient to cause inactivation. That this unique reactivity is conferred upon glu-58 by its specific environment is shown by the loss of reactivity with iodoacetate on denaturation of the protein.

Staphylococcal nuclease has been completely sequenced by Anfinsen and his associates (Taniuchi et al., ibid., 4759). It has 149 residues, is basic and has no disulphide bridges. Its most striking feature lies in the physical changes which occur when it interacts with competitive inhibitors. Cuatrecasas et al. (ibid., 4759) have found that binding of a nucleoside diphosphate in the presence of calcium ions (which are also required for activity) generates a sizable ultraviolet difference spectrum, arising from perturbation of tyrosine residues; moreover, spectrophotometric titrations show that their ionization is inhibited by the diphosphate, and finally a spectrophotometric method (solvent perturbation) shows that three or four of the seven tyrosines at the same time become effectively inaccessible. Although one cannot entirely rule out a direct interaction of all these tyrosines with the substrate, the observations are altogether consistent with a considerable convulsion in the conformation of the enzyme when the substrate binds.

Whether such a conformational change occurs, and its nature and extent, are, of course, general issues in enzymology. It is worth noting that the most direct evidence of such an effect emerges from preliminary X-ray data, just reported by Lipscomb's group on carboxypeptidase (Steitz et al., ibid., 4662). binding of a dipeptide generates quite considerable changes in electron density around the active site region. In lysozyme Phillips and his colleagues observed very small changes, whereas in pancreatic ribonuclease Richards' group found no significant changes at all in electron density of the enzyme when specific inhibitors were introduced. Their technique of diffusing substrates into the crystal in the diffractometer lends itself particularly well to precise determinations of small differences, and it must be concluded that in this case the conformation remains undisturbed. Evidently, therefore, generalizations about "induced fit" effects are not warranted at this stage.

Genetic Polarity

from our Cell Biology Correspondent

EARLIER this year, Imamato and Yanofsky found evidence that polar mutations in the lactose operon of *E. coli* cause a failure in transcription of the DNA beyond the mutation (see *Nature*, **215**, 1327; 1967). At the same time, there is strong evidence that polarity involves a failure in transcription. It is easy enough to reconcile these two sets of evidence because translation can control transcription by regulating the release of mRNA from the DNA template (see *Nature*, **214**, 228; 1967). So at least in organisms which have DNA as the genetic material, polarity seems to affect both transcription and translation.

Engelhardt, Webster and Zinder (J. Mol. Biol., 29, 45; 1967) and Capecchi (J. Mol. Biol., 30, 213; 1967) have now detected polarity in vitro with RNA from amber mutants of RNA bacteriophage. This result, together with Fink and Martin's work on polarity in the histidine operon of S. typhimurium (J. Mol. Biol., 30, 97; 1967), suggests that polarity is fundamentally a translational phenomenon which only incidentally involves transcription.

The RNA bacteriophages f2 and R17 are virtually identical. Both Zinder's group at the Rockefeller University and Watson's group at Harvard have

isolated amber mutants of f2 and R17, respectively, which have the amber mutation at the position of the codon specifying the sixth amino-acid in the phage coat protein. These mutants are polar in vivo. When E. coli is infected with the mutant, neither phage coat protein nor phage RNA replicase is made even though the RNA replicase cistron does not itself contain any mutation. This in vivo polarity could involve either transcription or translation because, of course, phage RNA is both replicated and translated in the cell (see Nature, 216, 639; 1967).

Both Engelhardt et al. and Capecchi programmed a cell free protein synthesizing system with RNA isolated from the polar mutants of f2 and R17 and asked, in the complete absence of any transcription, does the mutant RNA show polarity? Both groups found that with the correct ionic conditions in the cell free system the polar mutant RNA is indeed polar in vitro. Neither phage coat protein nor the other phage proteins are made. This clear cut result means that at least for the RNA phages polarity can be explained purely as a failure of translation. Spiegelman's recent report that phage RNA is replicated in the 3' to the 5' direction (see Nature, 216, 639: 1967) also supports this conclusion.

Fink and Martin have studied polar mutants in the histidine operon of S. typhimurium. This operon con-

tains six cistrons, and polar mutants in the first of the cistrons show a steep gradient of polarity. Those at the operator proximal, N terminal end of the cistron are strongly polar; those near the C terminal end are weakly polar and there is a fairly sharp transition from strong to weak polarity somewhere in the centre of the cistron. In all the subsequent cistrons, however, there is either no gradient of polarity or else a very shallow gradient. Polar mutants irrespective of their position in the cistrons show about the same degree of polarity.

This absence of a sharp gradient of polarity in all but the first cistron is the chief reason why Fink and Martin question simple transcriptional-translational models of polarity. They propose that once transcription has proceeded beyond a critical point in the first cistron it is uncoupled from translation. Any polar mutant beyond the critical region would not block further transcription and the polarity shown by such mutants would depend entirely on translational

processes.

There will be no satisfactory model to account for all the polarity phenomena which have already been observed in bacteria until more is known about transcription and translation. Polarity in the RNA phages, however, can now be explained solely by a translational model.

Magnetohydrodynamics and Power Generation

by
L. ROTHERHAM
Member for Research,
Central Electricity Generating Board

Recent reports of the plans of the Central Electricity Generating Board have caused some confusion.

MANY readers will be aware that for several years a very considerable research and development effort has been devoted by the Central Electricity Generating Board to studies of the generation of electricity by magnetohydrodynamic methods. Recently a decision was taken to reduce the magnitude of this work very substantially and it is of interest therefore to record some of the history of the project so that the reasons for beginning the work and now for its reduction can be noted and judged.

Work began in 1959, when the CEGB set up a small study group to examine the possible application of alternative methods of electrical generation to central power station use. In particular, preliminary and small scale experiments were begun on fuel cells, thermionic and thermoelectric devices as well as on magnetohydrodynamics. Obviously, a number of small scale studies such as this could not all be taken through to large scale development, and thermionic and thermoelectric devices were abandoned first, but both fuel cells and MHD were continued and the laboratory experiments increased in scale to involve installations costing a few tens of thousands of pounds.

Technically, the work on fuel cells proved to be of great interest and led to a very clear indication of the points where progress was needed, but with the effort available we were not convinced that these problems could be solved. It seemed unlikely, too, that costs could be achieved which would provide a competitive source of electrical generation, and the work finally stopped.

Studies were continued on MHD and by 1964 it was clear that many of the research problems were identified and that further progress would require large scale experimental work. An outline design of an MHD power station indicated that it would be competitive with nuclear stations (on the price assumptions current at that time) for several years provided that it could be brought into commission in the period 1975–1979. The difficulties of achieving this were recognized, but, in spite of the risk, the profit to be gained from a successful outcome was sufficient to persuade us to make the effort. The manufacturers of heavy electrical equipment (AEI, C. A. Parsons, English Electric, GEC), the Water Tube Boilermakers' Association and the National Coal Board generously joined in a collaborative pro-

gramme of research which has been constantly reviewed by a co-operative group. A very remarkable spirit of unity has prevailed since the first coming together of the collaborating groups all of whom have made substantial financial and technical contributions. It has been a constant stimulation and encouragement to me as chairman of the main committee to have the

support which has been so loyally provided.

The problems to be dealt with included the design of duct electrodes, air preheaters, combustion chambers for fossil fuels especially coal, seed recovery and recirculation, superconducting magnets and instrumentation and control problems. Much of the work could be carried out on small installations with burners of 2 to 40 MW ratings, but for some studies a larger rating of 200 MW was felt to be needed leading ultimately to a continuously running prototype. This latter part was the so-called Marchwood experiment since it was intended to be carried out at the CEGB laboratory at Marchwood.

Most of the small scale work has been highly successful and a good deal has already been published. Arrangements are being made to ensure that any further work will similarly be published as soon as possible. Satisfactory solutions can be seen to the problems of combustion and air preheaters although costs may be a little higher than had originally been contemplated. Also we have had a successful development of a superconducting magnet using a composite superconductor developed in collaboration with Imperial Metal Industries. This might be regarded as one piece of technical "fall-out" of some importance.

Work is incomplete, however, on seed recovery and on the development of proved long life electrodes (in this field there is a joint research programme with Electricité de France) although reasonable solutions seem to be in sight. This we shall establish within the next year by which time we believe that the research stage of the project can be regarded as completed with a not unreasonable measure of success. Whether any work will be continued after that time is an open question, but it is not likely to be substantial, since we cannot see the economic justification any longer for the large expenditure which the development stage would require.

The main reason for this is that the cost of nuclear power stations of the AGR type is still tending to fall while costs of fossil fuel fired plant are now tending to rise. This has brought closer the date at which an MHD station must be commissioned, and has reduced the period of time when it would be competitive with a nuclear station practically to zero. This and the delays in commissioning the Marchwood experiment have reduced the prospect of an economic return on the expenditure to a level so low that it is sensible to divert the resources to more promising activities.

It is easy to assess the costs of the work done in this joint study and the total must be about £2.5 m. It is more difficult to assess the benefits. There is some technical fall-out and there has been some stimulation of academic studies, but most important, perhaps, British manufacturers now have knowledge and skills derived from the joint study which will be of benefit if MHD development occurs elsewhere in the world.

GTP-stimulated Binding of Initiator-tRNA to Ribosomes directed by f2 Bacteriophage RNA

by JOHN S. ANDERSON* JAMES E. DAHLBERGT MARK S. BRETSCHER MICHEL REVELT BRIAN F. C. CLARK

MRC Laboratory of Molecular Biology, Hills Road, Cambridge

Binding of formyl methionyl-tRNA to ribosomes, directed by RNA extracted from the f2 bacteriophage, is dependent upon initiation factors, GTP and the presence of the formyl group. Binding of f2 RNA to ribosomes is, however, independent of initiating factors, amino acyl-tRNA and GTP.

THERE is much evidence that formylmethionyl-tRNA§ (F-Met-tRNA)1,2 participates in the initiation of protein synthesis in cell free systems of E. coli³⁻⁶. Messenger RNA containing the appropriate codon directs the binding of F-Met-tRNA to ribosomes. Such messenger activity

- * Postdoctoral fellow of the US Public Health Service. Present address: Department of Biochemistry, University of Minnesota, St. Paul, Minnesota.
 - † Postdoctoral fellow of the US Air Force Office of Scientific Research.
- † Present address: Institut de Biologie Physico-Chimique, Paris, France.

§ Abbreviations used in this paper include: GTP, 5'-guanosine triphosphate; GMP-PCP, 5'-guanylyldiphosphonate; ApUpG, adenylyl (3',5') uridylyl (3',5') guanosine; GpUpG, guanylyl (3',5') uridylyl (3',5') guanosine; F-Met-, formylmethionyl-; &RNA, transfer ribonucleic acid.

can be stimulated by the trinucleoside diphosphates ApUpG and GpUpG and by short defined oligonucleotides which contain these triplet sequences4.7-10. A natural messenger RNA such as that extracted from the f2 bacteriophage^{11,12} will also promote the formation of the initiation complex of F-Met-tRNA and ribosomes. Initiation factors¹³⁻¹⁵, which promote the *in vitro* incorporation of amino-acids into polypeptide products, enhance the ApupG-directed binding of F-Met-tRNA to This stimulated binding is greatest at a ribosomes16. magnesium ion concentration of about 5 mmolar¹⁷⁻²⁰, and is dependent on the presence of the formyl group 17,19 and

GTP¹⁸⁻²⁰. Initiation factors and GTP also stimulate the polyuridylate-directed binding of acetylphenylalanyltRNA^{21,22}.

The requirement for GTP in protein synthesis was first described by Keller and Zamecnik²³. There seems to be a stoichiometric relationship between the number of peptide bonds which are formed and the number of moles of GTP which are hydrolysed to GDP and orthophosphate²⁴. The β,γ-methylene analogue of GTP, 5'guanylyldiphosphonate (GMP-PCP), cannot be hydrolysed in this manner and is a competitive inhibitor of the GTP effect in protein synthesis²⁵. Formation of F-Met-puromycin and F-Met-phenylalanine by washed ribosomes supplemented with initiation factors and directed by ApUpG and ApUpGpUpUpU, respectively, required GTP26,27

In this paper we report that binding of F-Met-tRNA to ribosomes, directed by the natural RNA extracted from the f2 bacteriophage, is dependent on initiation factors, GTP and the presence of the formyl group at a magnesium ion concentration of 5 mmolar. Reaction of F-Met-tRNA with puromycin at a concentration of 5 mmolar magnesium ion is also dependent on the initiation factors and GTP. Although GMP-PCP can effectively substitute for GTP in binding F-Met-tRNA to ribosomes, it does not substitute for GTP in the reaction of F-Met-tRNA with puromycin. Binding of f2 RNA to ribosomes is independent of initiation factors, amino acyl-tRNA and GTP.

The preparation of ribosomes, initiation factors, 35S-F-Met-tRNA and 35S-Met-tRNA have been described before¹⁹. For separation of the two initiation factors, the crude initiation factors prepared through ammonium sulphate precipitation as previously described19 were dialysed against 0.01 molar tris-hydrochloric acid, pH 7.4, 0.002 molar magnesium chloride, 0.06 molar ammonium chloride and 0.006 molar β-mercaptoethanol (buffer A) and were applied to a DEAE-cellulose column (Whatman DE-52) which had been equilibrated with buffer A. One of the factors (F₁) was not adsorbed. A small amount of inactive material was eluted when the concentration of ammonium chloride in buffer A was increased stepwise to 0.10 molar. The second factor (F₂) was eluted when the concentration of ammonium chloride of buffer A was increased to 0.18 molar. The protein in these fractions was precipitated with ammonium sulphate (52 g/100 ml.). After centrifugation the precipitates were dissolved in buffer A and dialysed for 4 h at 4° C against three changes of buffer A. These dialysed preparations rapidly lost activity at 0° C. The preparations could be stabilized by storage either as suspensions in ammonium sulphate at 0° C or as aliquots of the dialysed fractions which were kept frozen in liquid

Growth and isolation of the f2 bacteriophage were carried out according to a slight modification by Lodish (personal communication) of a method described by Leberman²⁸. Purified f2 bacteriophage (55 mg) in 6 ml. of 0.2 molar potassium acetate, pH 5, was extracted with an equal volume of phenol saturated with 0.2 molar potassium acetate, pH 5. The aqueous phase was re-extracted with saturated phenol. The f2 RNA was precipitated from the aqueous phase by addition of three volumes of ethanol. The precipitate was recovered by centrifugation; it was redissolved in 1 ml. 0.2 molar potassium acetate, pH 5, and reprecipitated with three volumes of ethanol. The precipitate was collected by centrifugation. It was well drained and the remaining ethanol was removed at reduced pressure. The f2 RNA (17 mg) was dissolved in water to give a concentration of 4 mg/ml. and was stored in aliquots at -20° C until it was used.

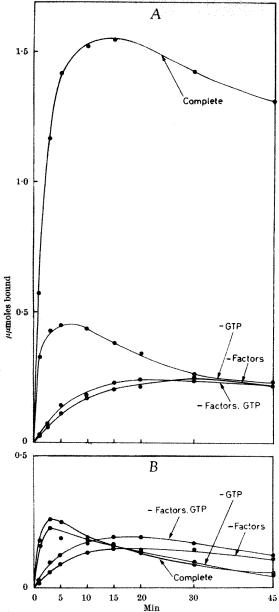

32P-labelled f2 bacteriophage was isolated according to the procedure of Lodish et al. 29 except that centrifugation at 40,000 r.p.m. for 2 h was substituted for 'Sephadex' chromatography. The RNA was extracted as described here. The specific activity of the RNA ($\sim 5 \times 10^5$ c.p.m. per ug) was reduced by the addition of unlabelled f2 RNA.

Assays for the binding of F-Met-tRNA and 22P-f2 RNA to ribosomes were performed according to established procedures 30,31 with only slight modifications. Reaction mixtures contained 0.1 molar tris-hydrochloric acid, pH 7.2, 0.05 molar potassium chloride, 0.01 molar ammonium chloride, and 0.005 molar magnesium acetate. amounts of ribosomes, initiation factors, f2 RNA and F-Met-tRNA are described in the legends of the figures and table. After incubation at 37° C, the reaction mixtures were diluted 50- to 100-fold with cold 0-1 molar trishydrochloric acid, pH 7·2, 0·05 molar potassium chloride. 0.005 molar magnesium acetate and were immediately filtered on 'Millipore' cellulose nitrate filters. The reaction tubes and filters were washed three times with 3 ml. portions of the same buffer. When dry, the filters were inserted into vials containing a scintillation solution of 0.4 per cent 2,5-diphenyloxazole (PPO) and 0.03 per cent 1,4-bis-2-(5-phenyloxazolyl)-benzene (POPOP) in toluene and were counted by liquid scintillation.

The RNA which can be extracted from f2 bacteriophage directs the binding of F-Met-tRNA to ribosomes13. At a concentration of 5 mmolar magnesium ion, both the rate and extent of this binding are significantly increased by the addition of initiation factors and GTP to the binding reaction mixture (Fig. 1A). The rate of binding of F-Met-tRNA to ribosomes is ten times greater in the presence of initiation factors and GTP than in their absence. Furthermore, the total amount which is bound is more than six times greater. The rate of binding of F-Met-tRNA in the presence of initiation factors but in the absence of GTP (Fig. 1A without GTP) initially approaches that observed in the presence of both components, but binding under these conditions rapidly reaches a maximum value which is considerably less than that of the complete system. The observed binding was dependent on the f2 RNA. Control curves (see legend to Fig. 1) for the four sets of conditions but without f2 RNA The nonformylatable showed essentially no binding. species, Met-tRNA_M, does not bind to ribosomes in the presence or absence of initiation factors and GTP at the low concentration of magnesium ions used in these experiments.

The results of similar experiments in which nonformylated 35S-Met-tRNA replaced the 35S-F-Met-tRNA are shown in Fig. 1B. It is evident that the nonformylated Met-tRNA binds much less than F-Met-tRNA in the complete system (compare Fig. 1A and B). Omission of GTP had little effect. Binding curves for 35S-Met-IRNA in the absence of initiation factors or in the absence of initiation factors and GTP were very similar to those obtained using F-Met-tRNA. The limited amount of binding of 35S-Met-tRNA was also dependent on the f2 These results show very clearly that maximal binding of the initiator tRNA at a concentration of 5 mmolar magnesium ion requires initiation factors, GTP, the formyl group, and messenger RNA, in this instance f2 RNA. Earlier we reported similar requirements for ApUpG-directed binding of the initiator tRNA19

The above results show that GTP plays a significant part in the formation of the binding complex of F-MettRNA with the ribosome. Because the GTP which is utilized in protein synthesis is hydrolysed at the B.ypyrophosphate linkage, and because the β,γ-methylene analogue of GTP is an inhibitor of protein synthesis, the ability of GMP-PCP to substitute for GTP in the binding reaction was investigated. The effect of the concentrations of GTP and of GMP-PCP on the amount of complex which is formed is shown in Fig. 2. These curves show that a final concentration of 0.2 mmolar GTP or GMP-PCP gives rise to a near maximal stimulation. It should be noted that the amount of F-Met-tRNA which is bound in the presence of GMP-PCP is frequently somewhat less than that bound with an equivalent amount of GTP. The curves of Fig. 2 and the time course for binding shown in Fig. 3A show that GMP-PCP does indeed support the

Min

Fig. 1. Requirement for the formyl group, initiation factors and GTP in the binding of Met-tRNA to ribosomes under the direction of f2 RNA. Components of the complete reaction mixtures (250 μl.) included 4.7 A₂₈₀ units of E. coli MRE 600 ribosomes, 4.7 A₂₈₀ units of F2 RNA, 50 μg of initiation factors, 0.23 mmolar GTP, and either 0.53 A₂₈₀ units of ²⁸S-F.Met-tRNA (38.2 μμmoles ²⁸S-methionine; 70 per cent formylated) (A) or 0.46 A₂₈₀ units of ²⁸S-Met-tRNA (33.5 μμmoles ²⁸S-methionine; less than 2 per cent formylated) (B). Incubation was at 37° C. At the times indicated 25 μl. samples were diluted with buffer and assayed as described earlier. The curves show the effect of omitting components. Examples of the amount of binding in μμmoles taken at the 15 min incubation point in control experiments which lacked f2 RNA for A and B were as follows: +factors+GTP, 0.06, 0.02; +factors-GTP, 0.02, 0.02; -factors+GTP, 0.04, 0.04; -factors-GTP, 0.03, 0.03.

formation of the F-Met-tRNA-f2 RNA-ribosome complex nearly as well as does GTP.

The components which are required for reaction of F-Met-tRNA with puromycin at a concentration of 5 mmolar magnesium ion were investigated. Fig. 3B shows that a rapid formation of F-Met-puromycin occurred if the reaction system contained F-Met-tRNA, ribosomes, 12 RNA, initiation factors, GTP and puromycin. Omission of any one of these components essentially abolished F-Met-puromycin formation. Whereas GMP-PCP is effective as a substitute for GTP in the binding assay (Fig. 3A), it is not an effective substitute for GTP in the reaction with puromycin. The rate of F-Met-puromycin formation

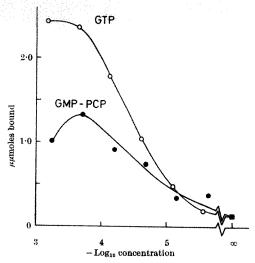

Fig. 2. Dependence of F-Met-tRNA binding on the concentrations of GTP and GMP-PCP. Each reaction mixture (50 μ L) contained 0-90 A_{260} units of ribosomes, 0-98 A_{260} units of f2 RNA, 17 μ g initiation factors and 0-14 A_{260} units of 38 S-F-Met-tRNA. GTP and GMP-PCP were varied to give the indicated molar concentrations. Incubation was for 10 min at 37° C.

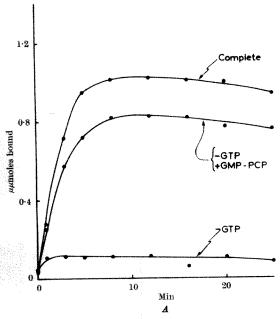

in the presence of GTP (0.32 $\mu\mu$ mole/min) is forty-five times greater than that observed with GMP-PCP (0.007 $\mu\mu$ mole/min).

Because messenger RNA is necessary for the binding of ²⁵S-F-Met-tRNA to ribosomes, an investigation was made of the requirements for the binding of 32P-labelled f2 RNA to ribosomes. Preliminary experiments indicated that crude initiation factors alone caused high levels of binding of 32P-f2 RNA to 'Millipore' filters even in the absence of ribosomes. In order to reduce this background, partially purified initiation factors obtained by chromatography on DEAE-cellulose were employed. Even the partially purified fractions F1 and F2 caused considerable background binding of ³²P-f2 RNA to 'Millipore' filters. Consequently, the amount of the purified factors was reduced as much as possible in an effort to minimize the background without significant alteration of the capacity of the factor preparation to stimulate f2 RNA-directed binding of 35S-F-Met-tRNA to ribosomes. The effect of initiation factors, GTP, and 35S-F-Met-tRNA on the binding of ³²P-f2 RNA to ribosomes is shown in Table 1. Comparison of the amounts of 32P-f2 RNA bound in the presence or absence of 35S-F-Met-tRNA (unfractionated tRNAs charged with 35S-methionine and nineteen 12Camino-acids) clearly shows that the amino acyl-tRNA has no effect on the binding of messenger RNA to ribosomes either in the presence or absence of initiation factors and GTP. Nor is the non-specific binding of 32P-f2 RNA to 'Millipore' filters by the initiation factors influenced by amino acyl-tRNA. The amount of ³²P-f2 RNA which is bound to ribosomes in the presence of initiation factors

The complete reaction mixture (50 μ l.) contained 0.90 A_{250} units of ribosomes, 0.47 A_{240} units of **P-f2 RNA (36,100 c.p.m.), 2 μ g of the F₁ initiation factor, 3 μ g of the F₂ initiation factor, 0.14 A_{240} units of **S-F-Met-IRNA (30,600 c.p.m., also includes all other amino acyl-IRNA species and 0.22 mmolar GTP. Incubation was for 10 min at 37° C. Reactions were diluted and filtered as earlier described. All **P values were corrected by the amount of **P-f2 RNA bound to the filters in the absence of both ribosomes and initiation factors (430 c.p.m.). All **S values were corrected for the energy spectrum overlap by **P.

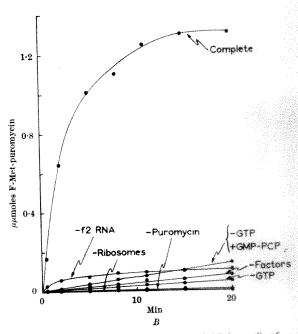

Fig. 3. A, Binding of F-Met-tRNA to ribosomes with either GTP or GMP-PCP. Reaction mixtures (250 μl.) contained 4-5 A₂₀₀ units of ribosomes, 4-7 A₂₀₀ units of f2 RNA, 100 μg of initiation factors and 1-72 A₂₀₀ units of ⁵⁵S-F-Met-tRNA. When present the GTP was 0-23 mmolar and the GMP-PCP was 0-22 mmolar. Incubation was at 37° C. At the intervals indicated 25 μl. aliquots were diluted with buffer and filtered. B, Requirements for reaction of F-Met-tRNA with puromycin. The complete reaction mixture (200 μl.) contained 0-1 molar and filtered. B, Requirements for reaction of F-Met-tRNA with puromycin. The complete reaction mixture (200 μl.) contained 0-1 molar tris-hydrochloric acid, pH 7-2, 0-05 molar potassium chloride, 0-01 molar ammonium chloride, 0-005 molar magnesium acetate, 0-22 mmolar tris-hydrochloric acid, pH 7-2, 0-05 molar principle. 0-01 molar ammonium chloride, 0-005 molar magnesium acetate, 0-22 mmolar tris-hydrochloric acid, pH 7-2, 0-05 molar principle. 0-01 molar ammonium chloride, 0-005 molar principle. 0-023 mmolar graph of initiation factors, and 0-86 A₂₀₀ units of ⁵⁴S-F-Met-tRNA charged with 19 μμmoles of ⁵⁴S-methionine of which 70 per cent was formylated. Incubation was at 37° C. At the indicated intervals 25 μl. aliquots were withdrawn and incubated with 50 μl. of 0-25 molar ammonium lacubation was at 37° C for 10 min. The alkaline hydrolysates were quantitatively applied to Whatman 3 MM filter paper and electrophoresed hydroxide at 37° C for 10 min. The alkaline hydrolysates were quantitatively applied to Whatman 3 Mm filter paper and electrophoresed for 50 min at pH 3-5 in 0-09 molar pyridinium acetate—acetic acid buffer with a potential of 60 V/cm. F-Met-puromycin migrated 6 cm towards the cathode and was located by autoradiography. All areas of the electropherograms with a mobility corresponding to F-Met-puromycin were cut out and counted by liquid scintillation.

and GTP is approximately the sum of that bound by the ribosomes alone plus that bound by the initiation factors and GTP without ribosomes (the background). These results suggest that binding of f2 RNA to ribosomes is independent of initiation factors, GTP, and amino acyltRNA. Clearly ³⁵S-F-Met-tRNA was bound when the system contained ribosomes, the initiation factors, GTP and f2 RNA, but not when any of these components were omitted. It is difficult to convert the data accurately from counts/min into µµmoles because the ³²P-f2 RNA was not necessarily intact (that is, in the 27S form). One molecule of F-Met-tRNA, however, was bound to the ribosomes/molecule of f2 RNA under these conditions. This is to be expected because the amount of f2 RNA was in excess of the amount of ribosomes²².

The high background of binding of f2 RNA in the presence of the initiation factors is of interest because a similar background was not observed for tRNA. This background could be reduced by the addition of unlabelled f2 RNA but not by the addition of unlabelled ribosomal RNA (J. E. Dahlberg, unpublished results). It is not clear if the interaction is specific for messenger RNA or if it just depends on the secondary structure of the RNA involved.

The initiation of protein synthesis involves several events occurring in sequence. One of the first events is the binding of messenger RNA to ribosomes. Results presented here indicate that the binding of messenger RNA to ribosomes is not dependent on the binding of **F.Met**-tRNA. Similarly, the initiation factors F_1 and F_2 and GTP seem to have no effect on the binding of messenger RNA. This agrees with the recent work of Revel and his colleagues³³. They have isolated a third protein factor which stimulates the binding of bacteriophage RNA to 30S ribosomal sub-units. Whether the messenger RNA binds directly at the codon for chain initiation and only at that codon is unknown. The results of Dahlberg and Haselkorn^{31,32} and Takanami et al.³⁴ show that such

specific messenger–RNA–ribosome interaction does occur. The suggestion has been made, however, that F-Met-tRNA is also involved in this specificity³⁵.

The GTP requirement for the F-Met-tRNA binding was not observed in much of the original work because the magnesium ion concentrations which were used were in the range 10-20 mmolar. At these concentrations F-Met-tRNA and Met-tRNA are bound to the oligonucleotide-ribosome complex without addition of GTP. Several groups have shown that accuracy in translation of messenger RNA is increased by using magnesium ion concentrations in the range 4-8 mmolar. Whether such concentrations approach physiological conditions more closely than do the higher concentrations which we used before for in vitro translation is not easily resolved. Nevertheless formation of the initiator–tRNÅ–ribosome complex occurs with f2 RNA at an optimum concentration of 5 mmolar magnesium ion, both in the absence and presence of initiation factors¹¹. The GTP requirement which is observed in the presence of initiation factors at 5 mmolar magnesium ion endows a stringent specificity for the formyl group. A similar requirement and specificity have already been reported where the trinucleoside diphosphates ApUpG and GpUpG were used instead of f2 RNA¹⁸. Recently other laboratories have also shown the requirement for initiation factors and GTP in the binding of F-Met-tRNA to an oligonucleotide-ribosomal complex18,20,36,37. It is generally agreed that at magnesium ion concentrations above 10 mmolar the enhancement of the binding reaction by factors and GTP becomes diminished or lost altogether.

The reaction of F-Met-tRNA with puromycin is analogous to normal peptide bond formation. Because both initiation factors and GTP are required to bind F-Met-tRNA, it follows that both the reagents must be present for the formation of F-Met-puromycin at 5 mmolar magnesium ion. The ability of puromycin to react with an acyl-tRNA has been taken as an indication that the

tRNA occupies the peptidyl-tRNA binding site on a ribosome³⁸. Although the F-Met-tRNA which is bound in the presence of GMP-PCP does not react readily with puromycin, the binding shows features which can be attributed to binding in the peptidyl-tRNA site. These include (1) a low magnesium ion requirement^{4,10}, (2) the dual coding of ApUpG and GpUpG for this tRNA4,10,10,10,10, and (3) the requirement for initiation factors which apparently do not influence the binding of amino acyl-tRNAs¹⁶. In spite of these considerations we cannot discard the single entry site model in which F-Met-tRNA first enters the amino-acid site and is subsequently shifted into the peptide site with the concomitant hydrolysis of We cannot explain why F-Met-tRNA, which, although bound in the presence of GMP-PCP, reacts very slowly with puromycin. It is unlikely, however, that hydrolysis of GTP is involved in the actual step of peptide bond formation because the F-Met-hexanucleotide fragment of F-Met-tRNA produced by the action of T₁ ribonuclease reacts with puromycin on the 50S ribosomal sub-unit without any requirement for GTP39. Furthermore, the puromycin reaction occurs at higher magnesium ion concentrations, that is, 10 mmolar, without any apparent requirement for GTP³⁸. If GTP were a source of energy for driving peptide bond formation, such a subtle change in the concentration of magnesium ions would not be expected to abolish the requirement.

We thank Dr K. A. Marcker and colleagues for their stimulating discussion of the work and Messrs W. A. Whybrow and B. J. Wayman for their skilful assistance.

Fitting Cosmological Models to the Radio Source Counts

by

W. DAVIDSON

Department of Applied Mathematics, University of Otago, Dunedin. New Zealand

Inspection of a properly formulated distribution for radio sources of local luminosity shows that the distribution is not as wide as has been thought. The distribution fits a Gaussian curve, with a standard deviation of one, to a good approximation.

No completely satisfactory or unique interpretation of the radio source counts by cosmological models has yet been achieved, but sufficient progress has been made to justify the optimism that it is now only a matter of time before this objective is reached. Because the counting of radio sources has demonstrated more clearly than any other test that the large scale features of the universe have evolved from an earlier denser state, it seems highly probable that, with an accepted explanation of the distribution of radio sources in depth, many questions in $cosmole\mathbf{g}y$ will be answered. In this article I shall discuss some important features of the problem which have emerged from recent investigations.

In view of the sustained evidence of a large scale isotropy in the distribution of the sources1,2, my early conclusion³ still holds. This is that in the past radio sources must have had a greater mean power than they have now, or they had a higher space density relative to

ordinary galaxies than is observed now, or (very plausibly) both these characteristics applied in some degree to the earlier radio sources. The problem is to determine the extent to which these evolutionary trends developed, and if possible to establish at the same time the geometry and kinematics of the underlying cosmological model.

It is now clear from the work already carried out4-7 that both "power evolving" and "density evolving" models can reproduce many features of the counts. In particular, the $\log N(S)$ against $\log S$ graph can be fitted quite closely on either hypothesis, provided an appropriate limiting epoch t^* and thus a limiting red-shift z^* for any given cosmolegical model is specified. The evidence acquired by Davies and myself from a representative range of models^{4,5,7} is that, if all classes of radio sources are allowed to evolve, then density evolving models (having no power evolution) require a significantly lower limiting red-shift z* than models evolving in power only. For

mixed models it became clear that the more density evolution there is relative to power evolution the lower z^* becomes, to such an extent that even in a model retaining substantial power evolution z^* had to be less than the red-shift of some recently identified quasars.

A significant discovery made by Davies and myself^{4,5} is that, in any model giving a satisfactory fit, the dispersion of power among the sources dominating the counts must have been much less in the past than that established from complete samples at high flux density S. This result has now been confirmed by Longairs, who found it impossible to fit the counts with the dispersion found at high S. Longair has taken the line that this indicates that only the high powered quasars have evolved, in either power or density, and that statistically the less powerful radio galaxies have retained the same mean power and space density relative to ordinary galaxies which they possessed at their first appearance in the universe. This particular hypothesis seems unlikely to be substantiated for at least two reasons. One is that the power distributions predicted for sources having $S \ge 20$ flux units in Longair's models (see his Fig. 7(c)) are at pronounced variance with the observed distribution for $S \ge 20$ flux units. The latter is shown in Longair's Fig. 5(a), and from wider statistical samples in Longair and Scott's* Fig. 7. As might be expected from Longair's hypothesis. there is a definite peak in the predicted distributions at $P_{178} = 10^{27}$ or 10^{28} W c/s⁻¹ ster⁻¹ which does not correspond to reality. It also seems that not enough power evolution has been allowed to take place in the range $10^{24} < P_{178} <$ 1026 W c/s-1 ster-1. Another argument against the hypothesis is that the recent work by Ryle and Longair, suggesting that the quasars, radio galaxies and normal galaxies are part of an evolutionary chain at a given epoch, may be interpreted as evidence against the possibility that statistical evolution with epoch is confined to quasars alone.

It seems more probable that, while the discovery of Davies and myself certainly implies a differential secular evolution among the different classes of radio source—presumably because intergalactic conditions affect the power, numbers and lifetimes of the sources—this evolution should be in the sense of narrowing down the power dispersion about the median power class observed at successively lower values of S. Because it seems certain from the earlier trials, and also from more recent evidence^{10,11}, that a successful model will incorporate at least some power evolution, this means that while the median power, in a given range of S, increases as S decreases, the numbers of sources on either side of the median must relatively diminish, whatever the rate of increase of their absolute numbers.

Such a trend does not exclude evolution in power at the higher end of the luminosity distribution. On the contrary, assuming that the quasars are at cosmological distances, because they all have large red-shifts those actually observed should properly be regarded as being chiefly outside the local luminosity distribution of radio sources, but may be interpreted in terms of a luminosity distribution the median of which moves upwards, although its dispersion is narrowing, as S decreases. A small contribution by high powered quasar type sources to the local luminosity distribution may, of course, be inferred if many local sources have passed through a quasar stage, even if none is observed locally at the present time.

It is therefore clear that what is taken to be the local distribution of radio sources is very important to the whole construction of evolving models designed to interpret the counts. Fortunately, it seems that recent systematic investigations into the distribution of power at high S contain the answer to this problem. Here I wish to make some observations which are relevant to model fitting, and to draw some conclusions from recent data which are not immediately apparent from the form in which they have been presented.

Adopting the terminology of Longairs, I shall distinguish between the local "luminosity distribution" and the local "luminosity function". In theory the former is the (arbitrarily scaled) frequency distribution, $n_0(P)$, of sources observed with S values exceeding some sufficiently high value S_0 . Thus $n_0(P)$ dP is proportional to the number of sources in the power range P to P+dP (at 178 Mc/s, say) with $S > S_0$, where \tilde{S}_0 is chosen as high as possible consistent with obtaining a local luminosity distribution from statistically adequate samples. local "luminosity function" is $\rho_0(P)$, where $\rho_0(P)$ dP is the number of sources in the range P to P+dPin unit volume of space at the present epoch. As has been shown in detail3,4, in any theoretical model which is spatially isotropic and in which an ideally smooth distribution of sources is assumed, there is the limiting relation as $S \to \infty$

$$n_0(P) \propto \rho_0 P^{3/2}$$
 (1)

In any such theoretical model, this relation will in fact be realized as $S \to \infty$, and so it is of basic importance to choose the correct scaling of $\rho_0(P)$ so that the theoretical log N against log S curve shall match correctly the observed data when evolutionary and statistical effects have been allowed for in the latter.

The relation (1), however, will correspond to, and can be matched with, reality in this way only if $\rho_0(P)$ can be determined from a tolerably small region of our neighbourhood, so that the static Euclidean approximations. implied in relation (1), can apply and will not be affected by the very evolutionary characteristics which we are trying to analyse. This means restricting the data as far as possible to radio sources identified within regions of small red-shift. In particular, the light-time must not exceed the average of individual radio sources by too many orders of magnitude. For the majority of sources a lifetime of between 106 and 107 years seems to be appropriate, and so an upper limit to the time lapse for suitable identifications will be about 5×108 years, corresponding to red-shifts z < 0.05 approximately. At this range the kinematic effects of red-shift are still small and cosmological densities are increased by a factor of only 1.16, which is probably a tolerable deviation from static uniform conditions.

At z=0.05, radio galaxies of absolute photographic magnitude, $M_{\rm pg}=-20.5$, have apparent photographic magnitude, $m_{\rm pg}\sim16$, and fortunately this is the limiting brightness above which complete catalogues of galaxies are available, for example, those of Vorontsov-Velyaminov and Zwicky. In a recent paper, Caswell and Wills¹² made use of these catalogues and a complete sample of radio sources of the 4C survey, having S>2 flux units, to establish the local $\rho_0(P)$ distribution in the range $3\times10^{22} \le P_{178} \le 10^{25}$ W c/s⁻¹ ster⁻¹. Below this, the $\rho_0(P)$ distribution in the range $10^{21} \le P_{178} \le 3\times10^{22}$ was given previously by Heeschen and Wade¹³. Thus in the range $10^{21} \le P_{178} \le 10^{25}$ the luminosity function $\rho_0(P)$ has been established from complete samples of galaxies having z<0.05, and therefore fully justifies the description of "local" in the sense required for model fitting. For $P_{178}>10^{25}$, W c/s⁻¹ ster⁻¹ identifications have to

For $P_{178} > 10^{35}$, W c/s⁻¹ ster⁻¹ identifications have to be made at higher flux densities if the sources are not to be located too far away to be considered local. It may, however, be calculated retrospectively that within a red-shift z=0.05 there are statistically only about 0.08 radio sources in one steradian, or about one in the whole sky, which have powers in the range $3 \times 10^{25} \le P_{178} \le 3 \times 10^{26}$ W c/s⁻¹ ster⁻¹. To obtain any statistics at all, identifications have therefore had to be used of galaxies having $m_{\rm pg} > 16$ and z considerably in excess of 0.05. In practice, the $\rho_0(P)$ for $P_{178} > 10^{25}$ W c/s⁻¹ ster⁻¹ has been calculated by Longair⁶ from the n(P) distributions⁸ in successive ranges of S down to S=15 flux units. For example, Longair⁶ presents a certain complete sample of forty-two sources having $S \ge 20$ flux units at 178 Mc/s,

thirty-eight of which have now been identified. Assuming that radio galaxies have $M_{\rm pg}=-20.5$ and that such sources having $m_{\rm pg}>20$ cannot usually be identified, it follows that identifications of radio galaxies are possible only if z<0.25. In this case, all sources of the sample having $P_{178}<1.2\times10^{26}~{\rm W}~{\rm c/s^{-1}}~{\rm ster^{-1}}$ should be identified, but of those having $P_{178}>1.2\times10^{26}~{\rm W}~{\rm c/s^{-1}}$ ster-1 some will have z>0.25 and lie outside the range of identifications. All those sources which have $P_{178}>1.2\times10^{26}~{\rm W}~{\rm c/s^{-1}}$ ster-1 and z<0.25 should be identified, but even within this red-shift there is statistically still only about one source in the whole sky of power $2\times10^{26}<P_{178}<3\times10^{27}$. As it happens, ten of the thirty-eight identified sources of the specified sample are quasars, having $M_{\rm pg}\sim-25$, with P_{178} ranging from 10^{26} to $2\times10^{28}~{\rm W}~{\rm c/s^{-1}}$ ster-1 and z values of order unity.

It is therefore to be concluded that because even at a red-shift z=0.25 the light-time is already about 2×10^9 yr, the $\rho_0(P)$ distribution for $P_{178}>10^{26}$ W c/s⁻¹ ster⁻¹ is precariously defined. This has been recognized by Longair, who for the purpose of model fitting simply guessed by extrapolation the local "luminosity function" for $P_{178}>10^{26}$ W c/s⁻¹ ster⁻¹, the plausibility of which was to be tested by comparing the predicted n(P) distributions with those observed at successive values of S. Evidently this procedure will be somewhat circular, because the necessary "evolution" to fit the observed distribution will depend on what has been postulated for $\rho_0(P)$. Unfortunately, it is just the doubtful range of $\rho_0(P)$ that Longair has chosen to evolve in his models. This error is likely to be considerably reduced if, in accordance with the view presented here, the median value of the local "luminosity distribution" is the dominant zero-point of departure for evolutionary trends.

A point I now wish to make is that it is questionable whether a correctly formulated "local luminosity distribution" is as broad as recently claimed by Longair⁶, or has as high a median power as can be inferred from the earlier work by Longair and Scott⁸. By the "local luminosity distribution" I mean the $n_0(P)$ distribution in the sense of satisfying relation (1). Already it seems that the latest information provided by Caswell and Wills¹² leads to a distribution in this sense which is significantly different from the observed n(P) distribution for $S \geq 15$ or 20 flux units. Fig. 1 reproduces the $\rho_0(P)$ distribution suggested by Caswell and Wills for the complete range $10^{20} \leq P_{178} \leq 3 \times 10^{27}$. Clearly backward extrapolation from high red-shift regions has had to be effected

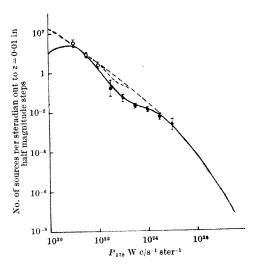

Fig. 1. The local luminosity function (full line) for the radio sources according to Caswell and Wills¹². This gives effectively the local source density $\varrho_0(P)$, expressed here as the number of sources in half magnitude steps per steradian out to a red-shift z=0.01. The new function corrects an earlier version by Longairs (broken curve). Full circles indicate data obtained by Caswell and Wills, open circles by Heeschen and Wade¹³.

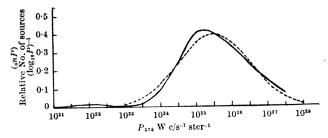

Fig. 2. The local luminosity distribution $n_0(P) \propto \varrho_0(P) P^{a/s}$ at 178 Mc/s as it would appear in a given range of high S in the Euclidean limit as $S \to \infty$, converted from the local luminosity function of Caswell and Wills¹². The ordinate is normalized so that it gives the relative number of sources per unit of $l(l=\log_0 P)$, that is, the ordinate is $\varrho_0(l)P^{a/s}$ where $\varrho_0(l)$ is number of sources $m^{-3}l^{-1}$, and $j\varrho_0(l)P^{a/s} dl=1$. The mode of the distribution is at $P_{17s}=1.5\times 10^{2s} \text{ W c/s}^{-1}$ ster⁻¹ and the median at $3.16\times 10^{2s} \text{ W c/s}^{-1}$ ster⁻¹. The Gaussian distribution (broken curve) shown for comparison has ordinate $(\sqrt{(2\pi)}\sigma)^{-1} \exp{-l^2/2\sigma^2}$ where σ has been chosen as unity and l=0 is taken at $P_{17s}=3.16\times 10^{2s} \text{ W c/s}^{-1}$ ster⁻¹.

to obtain $\rho_0(P)$ for $P > 10^{26}$ W c/s⁻¹ ster⁻¹, but the shape of the associated $n_0(P)$ curve is only marginally sensitive, within the likely error, to these approximations at high P (see further comment later). In Fig. 2, I have plotted the $n_0(P)$ distribution, calculated in the sense of relation (1) from Caswell and Wills's $\rho_0(P)$ function. The ordinate is normalized to give the relative number (fraction) of sources per unit of $\log_{10}P$ at each value of P. Thus, if the distance along the horizontal axis is measured in units of $l = \log_{10}P$, the total area under the graph is unity. For comparison I have also shown a log-Gaussian curve to the same scale, its equation being

$$n(l) = \frac{1}{\sqrt{(2\pi)}\sigma} e^{-l^2/2\sigma^2}$$
 (2)

where σ has been chosen equal to unity.

It is seen that a Gaussian curve with standard deviation unity is still, for theoretical purposes, an adequately close approximation to the local "luminosity distribution", contrary to Longair's claim that "the better estimates of the luminosity distribution indicate that it is much broader and flatter than a Gaussian". Moreover, it is to be observed that the median \bar{P}_{178} of the Gaussian curve of best fit is at about $3\cdot 2\times 10^{25}$ W c/s⁻¹ ster⁻¹, while the mode of the actual $n_0(P)$ distribution is even less at about $1\cdot 5\times 10^{25}$ W c/s⁻¹ ster⁻¹. In Fig. 3 the $n_0(P)$ distribution (broken curve) is contrasted with the observed n(P) distribution given by Longair and Scott* for $S\geq 15$ flux units. The latter is drawn with the same normalization for $n_0(P)$. The Long ir–Scott curve has a mode-median of about $P_{178} = 8\times 10^{25}$ W c/s⁻¹ ster⁻¹.

It is to be concluded therefore that the local luminosity distribution on which we must regard past-directed evolution to operate is neither as broad nor as high powered as has been thought in the past. On the contrary, the evidence is that already at $S \geq 15$ flux units the n(P) distribution has evolved away from the $n_0(P)$ distribution. Furthermore, a lower value for \bar{P} than previously assumed implies a somewhat smaller distance scale for the unidentified sources.

Even with the $n_0(P)$ curve given in Fig. 2 there is evidence that a degree of cosmological error in estimation is still present at higher powers. Calculation shows that for the Caswell and Wills $\rho_0(P)$ function, given in Fig. 1, the integral $\int \rho_0(l) P^{3/2} dl$ in the range $10^{20} < P_{178} < 3 \times 10^{27}$ W c/s⁻¹ ster⁻¹ is about 2.8×10^{-36} , $\rho_0(l)$ being expressed in sources $m^{-3}l^{-1}$. If the limiting relation (1) applied at high S, then the corresponding N(S) would be

$$\frac{1}{3} \, \times \, 2 {\cdot} 8 \, \times \, 10^{-36} \, S^{-3/2}$$

At S=35 flux units this would yield $N\sim 4.5$ ster⁻¹. The observed count down to S=35 flux units is $N=4\pm0.8$ ster⁻¹. Because the total sky count for this range includes

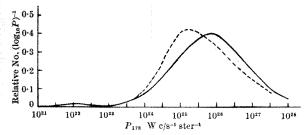

Fig. 3. The luminosity distribution according to Longair and Scott*, as observed among radio sources having flux density in the range $S_{178} \ge 15$ flux units and emission power $10^{21} < P_{178} < 10^{28}$ W c/s^{-1} ster $^{-1}$. The median and mode of the distribution are both at about $P_{178} = 8 \times 10^{28}$ W c/s^{-1} ster $^{-1}$. The local distribution $n_b(P)$ of Fig. 2 is also shown for comparison (broken curve).

sources of considerable red-shift, for example, 3C 295 and 3C 298, which have flux densities S_{178} equal to 73 flux units and 44 flux units with red-shifts 0.46 and 1.44, respectively, it is indicated that a value of 2.8×10^{-36} for $A = \int \rho_0 P^{3/2} dl$ is still probably a little too high. Indeed, an extrapolation of Gower's curve of the complete counts to date, for example, down to $S \sim 100$ flux units, can produce a value for A as low as 2×10^{-36} . At S = 35 flux units this would yield a Euclidean count of about 3.2 ster-1, which is still not outside the error range for the observed count at 35 flux units.

Attempts at fitting cosmological models to the counts of radio sources indicate that the dispersion of power must narrow into the past, presumably because intergalactic conditions affect the powers, numbers and life-

times of the sources. Inspection of a properly formulated "local luminosity distribution" for radio sources shows that it is not as wide as has been thought and that a Gaussian curve having $\sigma=1$ is still a good approximation to it. Moreover, the median power P_{178} is no more than about $3\cdot2\times10^{25}$ W c/s⁻¹ ster⁻¹, while the mode is at $1\cdot5\times10^{25}$ W c/s⁻¹ ster⁻¹, and there is evidence that at $S_{178} = 15$ flux units the sources have already "evolved". It seems certain that to explain the counts "power evolution" into the past will be necessary, although there may also be some limited "number evolution". Although the former effect gives a relatively greater distance scale for the unidentified sources, the value of \bar{P} now suggested may well require a limiting red-shift z^* for the sources of no more than 3. It is indicated that whatever the evolution has been, it is not confined to quasars.

Correlation between Marine and Terrestrial Pleistocene Successions

N. J. SHACKLETON C. TURNER

Sub-department of Quaternary Research, University of Cambridge

Using evidence from cores from Marks Tey, Essex, it is concluded that the glacial cycles suggested by Emiliani give a much truer picture of the chronology of glacial events in Europe than those suggested by Ericson et al.

NOBODY today would seriously attempt to review the methods available for dating the glacial events of the Pleistocene without considering the evidence which has been obtained from the study of deep-sea cores. The reason is that it is only in the relatively stable environment of the ocean bed, far from land, that continuous successions are to be found. It is therefore most unfortunate that two of the most widely quoted interpretations^{1,2} of the deep-sea evidence should differ so enormously; the two interpretations are compared in Fig. 1. In connexion with this figure, two points must be clarified.

First, the discrepancy in interpretation is in no part caused by differences in the absolute dating of the events recorded in the cores; over the upper 400,000 yr the two interpretations have in part been derived from identical material3. Second, the shorter chronology proposed by Emiliani is in no way incompatible with dates of well over 106 years which have been obtained for glacial events in several parts of the world, or with the dating of the base of the Pleistocene at about 2×10^6 years (ref. 5), because he has not yet examined in detail material relating to the earliest periods.

If we accept the fact that cross-correlation between deep-sea cores is a valid procedure, the deep-sea record becomes a yard-stick against which Pleistocene events may be dated. The difficulty lies in the recognition of terrestrial climatic events in the marine record. For this purpose, the definition of the terms "glacial" and "interglacial" must be framed in such a manner that the events which they define may be recognized in a sequence of marine deposits. For example, evidence for a custatic fall in sea level of 100 m or more could be regarded as a suitable criterion by which to recognize a glacial episode.

Unfortunately, in deep-sea deposits the direct evidence for change in sea level is masked by other effects, while stratigraphically long sequences of undisturbed sediment are not generally available from shallower water. It has recently been shown, however, that the abstraction of large quantities of isotopically light water from the oceans to build up continental ice sheets results in an easily detectable change in the isotopic composition of the oceans. Thus isotopic analysis provides a convenient means for identifying glacial events in a marine sequence.

The definition of the term "interglacial" is less straight-Suggate has tackled the problem, and has provided a definition which many workers find useful. By his definition, "interglacial" implies both the melting of ice sheets to about their present level, and the maintenance of a warm climate for a sufficient length of time to permit certain vegetational changes to take place. According to this definition, the length of Postglacial time has been sufficient to characterize the present as "interglacial" rather than "interstadial".

It is clear that, according to this definition, zone x of Ericson *et al.*, or core stage 5 of Emiliani, represents an interglacial, because isotopically it appears similar to the present, implying the melting of ice sheets, while its duration was about 30,000 yr (ref. 10). Presumably it may appropriately be identified with the Last Interglacial.

The interglacial before last is identified in the Ericson chronology with zone t, which had a duration of about 600,000 yr (ref. 5). If we consider as an alternative that zone x represents the last interglacial, as already suggested, then zone v, with a duration of about 250,000 yr, must represent the previous interglacial. According to Emiliani's scheme, his core stage 7, with a duration of about 50,000 yr, should be identified with the penultimate interglacial. It seems that research into the Pleistocene could be seriously hampered by the acceptance of an estimate for the duration of an interglacial which could be in error by a factor of ten.

For this reason, an estimate of the absolute time span of the interglacial before last would be of critical importance, though its absolute age may not be known. In this connexion the evidence which has been obtained from the complete sequence through the Hoxnian interglacial at Marks Tey would seem to be crucial.

At Marks Tey, Essex, a series of Pleistocene lacustrine deposits infill a narrow trough, floored with boulder clay but cut into the subglacial surface. Pollen analysis has shown that continuous deposition took place in this basin from Lowestoftian Late-glacial to Gipping Early-glacial times, that is to say throughout the Hoxnian¹¹.

A borehole at the Marks Tey brickworks, put down near the deepest part of the lacustrine basin, yielded a particularly interesting stratigraphy. Beneath a thickness of Gipping Early-glacial clays there occurred finely but evenly laminated organic clay-muds, which were shown

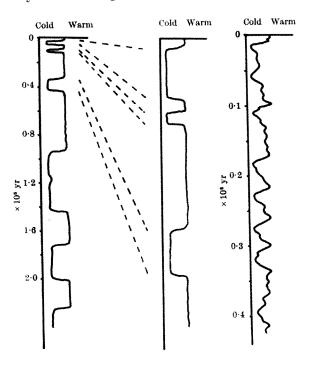

Fig. 1. Left: Pleistocene record in deep-sea cores, according to Ericson et al.¹ (as recently modified*). Centre: Upper part of left-hand curve, expanded time scale. Right: Generalized temperature curve according to Emilian¹, time scale as centre curve. The left and centre curves are based on the abundance of the foraminiferal species Globorotatia menardii, according to the method described by Ericson and Wollin². The right-hand curve is based on the relative abundance of the oxygen isotopes in the tests of planktonic foraminifera. The time unit is 10° years for all curves; the zonations are those of the workers cited (see ref. in text).

by pollen analysis to have been deposited during the Pre-temperate and Temperate zones of the Hoxnian interglacial. Unfortunately, the uppermost portion of these laminated clay-muds had been disturbed by slumping and consequent brecciation in this boring, although undisturbed deposits, covering the complete latter part of the Hoxnian interglacial, are well preserved elsewhere in the basin.

The general stratigraphy at this point, from borehole and brickpit sections, is

F about	22 m	Grey silty clay, generally	Early-Gipping
E	5·3 m	laminated Brecciated, finely lamin-	Hoxnian Zones III a-b, ? IV
D	6·5 m	ated organic clay-mud Finely laminated organic	111 a=0, . 1 ·
		clay-mud The upper 4·5 m evenly and distinctly	Hoxnian Zones II c and III a
		laminated Below this more finely and so less distinctly	
		laminated Becoming more poorly laminated towards	Hoxnian Zone I
C	1.3 m	the base Grey clay, sometimes shelly	Late-Lowestof- tian
B A		Sand and fine gravel Poulder clay (not proved in this boring)	

The upper, Gipping grey clay (F) shows clay-silt lamination akin to glacial varves. The rhythmic lamination structures of the underlying clay-mud are of an entirely different nature. Fine, silty, organic laminae alternate distinctly and regularly with grey, buff-yellow or white laminae, each lamination pair being generally less than 1 mm thick.

These structures have been examined in thin section. Where well developed, two features emphasize the lamination of the clay-mud: (1) the regular deposition of distinct layers of the crowded frustules of the diatom Stephanodiscus astraea var. minutula (the light laminae); (2) the gradually increasing deposition of organic material following the period of diatom deposition, leading to the production of darker intervening laminae. It is difficult to demonstrate fluctuations in the precipitation of calcium carbonate during this sedimentation cycle, because the matrix of the entire sediment consists of that material. Nevertheless, a period of high calcium carbonate precipitation seems to have taken place immediately after the formation of the diatomaceous layer, because this is generally overlain by a thin, almost pure layer of calcite crystals also contributing to the light laminae.

Both calcium carbonate deposition and diatom flushes are known to have a seasonal rhythm in modern lakes. Calcium carbonate deposition is at a maximum in spring and early summer as an indirect effect of rapid plant growth, photosynthesis and rising temperature on the carbon dioxide balance in lake waters¹². Lamination structures formed by the precipitation of annual laminae of calcium carbonate in this way have been described from sediments of the Faulenseemoos near Spiez, Switzerland¹³, and from lakes in Ontario¹⁴.

In North German lakes today, Stephanodiscus astraea is known to produce flushes in late winter and early spring, although it is present in the plankton throughout the year. Although usually annual, these flushes are probably controlled by nutrient conditions rather than by temperature.

Further work, possibly finer pollen analyses, will be necessary to give definite indications of the annual or non-annual origin of the lamination structures at Marks Tey. On balance their apparent cycle of deposition

corresponds to known annual sequences of depositional events in modern lakes. It would certainly be difficult to invoke longer cycles of, say, 5, 10 or even 50 yr to

produce such regular sedimentary features.

A total of 4,486 lamination pairs have been counted from cores from the top 4.46 m of the undisturbed claymud (D), where lamination was best developed (possible counting and sampling error under 10 per cent). This stratum covers a sizable part of the temperate period of the Hoxnian interglacial (pollen zones II b and most of III a, see Fig. 2). In the clay-mud below this the lamination structures are finer and cannot be counted accurately, but a reasonable estimate is that between 5,000 and 10,000 lamination pairs are represented. The composite pollen diagram, Fig. 2, shows the extent of these laminated portions of the interglacial deposits within the context of the vegetational succession of the whole interglacial. The vertical scale of this diagram is based on thickness of deposition and suggests that the latter part of the Hoxnian interglacial, from which we unfortunately have only brecciated or unlaminated deposits, occupied a similar period of time to the earlier part already discussed.

If the lamination features prove to be annual, then both the nature and time-scale of the vegetational changes which took place during the early part of this interglacial are closely paralleled by those of the Flandrian Postglacial period. An estimate for the total length of the Hoxnian interglacial period would be of 30,000–50,000 yr. The only other direct assessment of the duration of an interglacial period is that of 27,000–35,000 yr from the possibly Cromerian deposits at Bilshausen, Germany¹⁸, again a figure based on lamination structures.

It should be emphasized, at this point, that there are no signs of any important unrecorded vegetational or sedimentary hiatus within the Hoxnian deposits at Marks Tey. Furthermore, clear stratigraphic evidence exists there for truly glacial conditions preceding the Hoxnian interglacial, and likewise for severely arctic conditions succeeding it, although the site was never actually reglaciated. The vegetational evidence from Marks Tey provides a conclusive correlation of the Hoxnian with the Holstein interglacial on the Continent. Nowhere in North-western Europe does the vegetational record of this interglacial support such conjectures as a two-phase

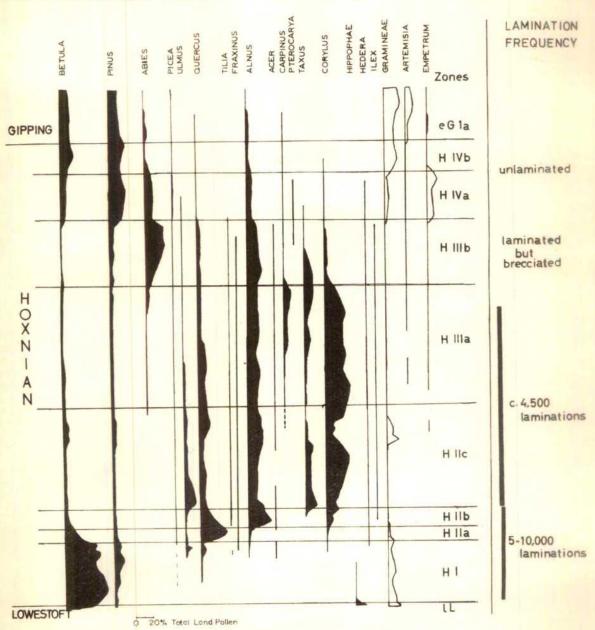

Fig. 2. Hoxnian vegetational succession at Marks Tey, Essex.

penultimate interglacial interrupted by a cool interval. or the more complex subdivisions sometimes interpreted from the study of river terraces¹⁶. There is no evidence to support the application of the old term "Great Inter-glacial" to the penultimate interglacial as it is now

defined and recognized.

It is quite clear that the evidence for the duration of the Hoxnian interglacial, as recognized here, is compatible in scale with the oxygen isotope chronology proposed by Emiliani, but not in any sense with that proposed by Ericson et al. and modified by Glass et al.5. The same may be said for the evidence obtained from Bilshausen 15. The fact that the record obtained by Emiliani is more complex than the classical picture of the timing of the Ice Ages cannot any longer be taken to imply that it is in error. On the other hand, it does imply that identifying named terrestrial events with recognized points in the marine sequence can only be done with the aid of accurate absolute dates, as Emiliani has pointed out2. It is not sufficient to identify the largest events with the best known names and leave it at that, as seemed tempting when marine sequences first became available; this is especially true in view of the fact that the glacial successions are not definitively established even in the Alps and Northern Europe.

We are therefore forced to the conclusion that although Glass et al.5 have obtained a complete and reproducible sequence through the two million or so years of the Pleistocene, the micropalaeontological record which they have obtained bears little relation to the chronology of glacial events in Europe. In contrast, although Emiliani's oxygen isotope chronology may only span about one-fifth of the duration of the Pleistocene, it records glacial cycles on the scale at which they occurred in Europe.

One of us (C. T.) thanks the Royal Society, who made a grant for the sinking of boreholes at Marks Tey. We are both most grateful to Dr R. G. West for his stimulation

and advice during the writing of this paper.

Shatter Cone Orientation at Gosses Bluff Astrobleme

ROBERT S. DIETZ

Institute for Oceanography, ESSA. Miami, Florida

Shatter cones caused by shock fracturing are widely developed at the Gosses Bluff cryptoexplosion ring structure in central Australia. The force field can be reconstructed whereby the applied shock arrived centrally and from above, which is consistent with a cosmic impact. For this and other reasons, Gosses Bluff is an astrobleme.

Gosses Bluff is an isolated ring structure of upturned Lower Palaeozoic rock nearly 3 miles across, situated in the Amadeus Basin of central Australia, about 200 km west of Alice Springs. It rises about 700 ft. above the surrounding plain and is breached by an intermittent stream, on the north-east side. The term "bluff" is something of a misnomer, or at least is an inadequate description.

The interior bowl shaped basin might well be misinterpreted as a modern meteorite crater (Fig. 1). It is, however, at the same level of erosion as the surrounding plain and is not depressed, and there are no remnants of lake beds which would indicate that a former closed basin existed here. Furthermore, geological inspection shows that it is the upturned ring of a great dome, the soft centre (Larapinta) of which has been erosionally gutted, forming the central bowl. Lining the bowl, the cliff-forming Meerenie sandstone now stands etched out in high bold relief and is in turn surrounded by the Pertnjara formation.

If Gosses Bluff is to be interpreted as a meteorite structure, then it can only be regarded as an astrobleme-an ancient cosmic impact scar, with the bluff per se being the uplifted central dome of a much larger circular structure. Although the strata are largely hidden from view outside the bluff, this interpretation is quite permissible. Gravity and magnetic surveys at the Bureau of Mineral Resources show that the bluff marks the centre of a circular deformation 12 miles wide. A structure of this size is also apparent

as a double "ghost ring" on a Gemini IV photograph from near space (Fig. 2).

On the basis of much evidence of explosive force, Crook and Cook1 rejected an earlier view which was widely held, that Gosses Bluff was a salt diapir: while agreeing that it was of cryptoexplosive origin, Crook regarded it as an astrobleme and Cook thought it was cryptovolcanic.

Fig. 1. Aerial oblique view of Gosses Bluff looking south, showing the ring of upturned strata,

Fig. 2. Gemini photo of Gosses Bluff from near space. Dark circle in centre marks the upturned ring of rocks 2.5 miles across. Note "ghost ring" surrounding Gosses Bluff which identifies the full extent of the structure, 12 miles across.

Cook² has since revised his opinion and concurs in the astrobleme interpretation. Daniel Milton and Robin Brett, who are at present mapping this structure in detail as a joint project of the US Geological Survey and Australian Bureau of Mineral Resources, also regard it as an astrobleme. Their results will soon be published. This article is limited to a discussion of shatter coning at Gosses Bluff which further supports this interpretation.

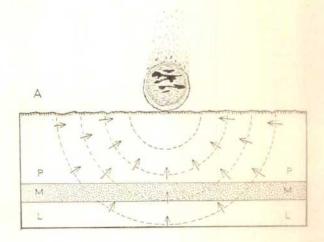

Shatter cones (Fig. 3) were first noted by Crook and Cook, who, however, regarded them merely as an incidental aspect of the structure with the orientation of the shatter cone being random. Actually, Gosses Bluff is the most intensely shatter coned of the eighteen sites I know around the world⁴ and the cones show a high degree of preferred orientation which reveals the shock force field impressed on the structure. Crook and Cook also doubted the validity of shatter cones as a criterion for astroblemes, but I have attempted to answer their objections elsewhere⁵.

In order to study the shatter cone orientation and distribution at Gosses Bluff, I made several spoke-like traverses of the structure commencing at the centre (ground zero) and working radially outward. Shatter coning was found to be extensively developed throughout the structure on a scale which I have never before observed,

Fig. 3. A group of shatter cones from the Pertnjar a formation showing orientation oblique to bedding.

with the possible exception of the Vredefort Ring of South The coning is least developed in the southern quadrant and most strongly developed in the northern quadrant where, in places, nearly all rock talus revealed shatter coned faces. There is also a strongly preferred orientation of the cone apexes. In the vertically dipping Larapinta formation of the central basin and in the Meerenie sandstone marking the interior "lining" of the uplifted ring, the shatter cones are oriented radially outward—that is, normal and upward with respect to bedding. Further out from ground zero (4,000-7,000 ft.) in the Pertnjara formation, the shatter cones point generally outward but only at angles of about 60° upward with respect to bedding. Still further out, at two sites, shatter coning is oriented upward and parallel to bedding. The first of these two sites occurs close to the spot where the road track enters the breach in the bluff ring at a position about 10,000 ft. north-east of ground zero. The other site is a hogback, fully detached from the ring proper and lying about 13,000 ft. north-west of ground

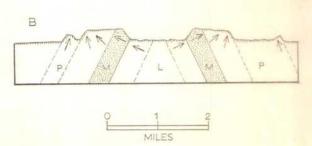

Fig. 4. Diagrammatic representation of shatter cone orientations at Gosses Bluff revealing the shock wave force field which was impressed on the structure. A. Impact of bolide and radial spreading of shock wave instantaneously prior to upheaval. L. Larapinta group; M. Meerenie sandstone; P. Pertnjara formation. B. Presently observed orientation of shatter cones (arrows) in upturned strata. Vertical exaggeration, 2:1.

If one can envision a return of the rocks to their presumed pre-event, essentially horizontal position, we observe a pattern of shatter coning which reconstructs the shock wave force field which acted on the structure (Fig. 4). Before upheaval the shatter cones in the central region pointed directly skyward, those farther out pointed inward and upward, while those farthest out pointed radially inward. Because the apices of shatter cones point toward the impressed shock wave front, this indicates a shock originating from above as, most likely, the impact of a cosmic body with an apparent or effective diameter (that is, for purpose of impressing a parallel shock front) of about 7,000 ft. This derived diameter may well be beyond the limits of resolution of the

method and the object could have been much smaller because we are now examining an inverted mass of rock. The strata now at ground zero were originally positioned several thousands of feet deeper. This effect tends to enhance the normal and upward-to-bedding aspect of shatter cones. Nevertheless, the apparent diameter of the bolide would seem to have been at least a few thousand feet.

As elsewhere, there are exceptions to the preferred orientation noted here, but these are sufficiently few to be regarded as uncommon. Most often, fully inverted cone orientations are found; more rarely the cones point randomly. It is necessary, of course, to distinguish positive cone faces from negative ones and to measure the apical direction of a full 360° cone rather than the directions of various cone segments; otherwise confusion results, giving a false appearance of randomness. According to the impact interpretation, random and inverted orientations may be ascribed to the reflexion of shock waves which were still sufficiently intense to cause shatter

Outcrops in the outer annulus of the structure, and peripheral to Gosses Bluff proper, are few and far between. Those outcrops which were found were searched; no shatter cones were found. Possibly at this range of from 2 to 6 miles from ground zero, shock pressure had already dropped below the level required to produce shatter coning (20 to 80 kbars). It would not be surprising, however, if a further search revealed some shatter coning on a reduced scale. This places Gosses Bluff in an intermediate position among known shatter coned structures, in most of which shatter coning is confined to the central eye (for example, Serpent Mound, Ohio) and the very large astroblemes where shatter coning extends outward, 15 miles or more (Sudbury, Vredefort Ring).

At seven sites around the bluff, I found nests of breccia containing shatter coned fragments. In no case does the shatter coning extend into the breccia matrix. This is expected for an astrobleme because, in a cosmic impact, the target is first engulfed by the shock wave, followed almost instantaneously, but clearly separated in time, by brecciation and upheaval.

The bluff is circular in its external limits: the interior plan, however, as outlined by the Larapinta and Meerenie formation, has the form of an equilateral triangle with truncated basal angles and with a sharp apical angle to the north, giving the internal structure an overall pentagonal form. An imaginary line running from north to south through the apex provides an axis of bilateral symmetry. Such bilateral symmetry is a well known aspect of some other astroblemes3 and it could reflect the arrival of the bolide at an oblique angle from the south and towards the north. Shatter coning is clearly more intensely developed at the northern apex of the structure than elsewhere.

While I remain convinced of the astrobleme interpretation, numerous questions remain unanswered. what was the original form of the crater? Second, why is the central dome so large (about 3 miles) and uplift so great (about 10,000 ft.) with respect to the overall 12 mile diameter of the structure? One suggestion is that the cosmic bolide was a comet head combining sufficient excessive hypervelocity and low density to provide for a surface or very shallow detonation which enhances the central uplift effect6. Third, what is the age of the structure? As Crook and Cook point out, Gosses Bluff appears to have been exhumed after early Tertiary peneplanation so that a Mesozoic age seems reasonable.

I thank Milton, Brett and George Berryman for hospitality and the Bureau of Mineral Resources of Australia for logistical support.

Molecular Shape and Odour: Pattern Analysis by PAPA

by

J. E. AMOORE

Western Regional Research Laboratory, Agricultural Research Service. US Department of Agriculture, Albany, California

G. PALMIERI E. WANKE

Istituto di Fisica, Università degli Studi, Genoa, Italy

The PAPA pattern recognition machine, consisting of an image dissector and computer, can rapidly and accurately make comparative measurements of molecular model silhouettes. This will be most useful for research on the stereochemical specificity of the sense of smell.

THERE is evidence that the specificity of the human sense of smell depends very largely on the molecular shapes of odorous compounds1-3. A successful but tedious manual method of measuring molecular shape was worked out by Amoore³. On each of three silhouette photographs of a scale molecular model, the molecular shape was estimated from measurements of thirty-six radii of the molecule (Fig. 1). This may be called the "manual radius method". It measured the molecular shape of the test compound in terms of its overall similarity to the molecular shape of a standard compound.

Professor A. Borsellino suggested to us that the molecular silhouettes could be scanned and computed automatically by the PAPA pattern recognition machine evolved by Palmieri et al.⁴⁻⁸ (PAPA, Probabilistic Automatic Pattern Analyser). The instrument scans the molecular silhouette with a reproducible collection of 4,096 random lines, many of which will intersect the silhouette (Fig. 2). This may be called the "PAPA intersection method". It can express the similarity in molecular shape between a test compound and the chosen standard. We have found that 1,600 comparisons of molecular silhouettes, which had previously taken about 3 months by hand, may be accurately accomplished by the PAPA machine in 3 hours.

The pattern recognition machine consists of three sections: an input, a computer and an output. In the input the patterns are surveyed to extract the required information, by measuring the most prominent features of the pattern. During the instruction phase, when known examples are displayed, these data are stored in the computer. Conversely, during the recognition phase, the features of an unknown pattern are compared with the information previously memorized, and the similarity between the unknown pattern and the learned examples is computed. At the output the results of the calculation are printed as a probability value, or converted to a classificatory decision.

In the PAPA machine the patterns are analysed by means of random lines called associative units (A units). There are various ways of generating and storing these random lines. They may be obtained from a special pseudo random noise generator. Its output arises from a digital to analogue transformation (operational summing and passive integration) of the random square wave signal of several feedback-shift-registers. Special gates prevent the lines from going beyond the frame border. Two generators are used for the X-Y scanning, which is reproducible, because the circuits are essentially digital and therefore resettable.

Each random line intersects the pattern a variable number of times, and a threshold circuit generates a binary signal according to one of several alternative criteria: counting the number of intersections (intersection method), or the numerical parity (even or odd); measuring the widths of the intersections (area method), or the time intervals between them. The whole set of binary signals is stored for every A unit, while all the examples of one class are being shown to the machine, and a description of that class is formulated with increasing accuracy. Different descriptions are subsequently obtained for each of the other classes of pattern presented. It should be understood that each and every pattern, known and unknown, is scanned with the same set of random lines, which allows direct comparisons to take place in the computer.

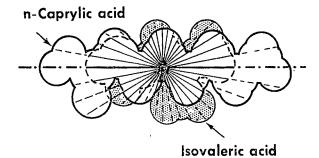

Fig. 1. The old manual radius method for measuring molecular shape. Top silhouette photograph of the elongated molecule of n-caprylic acid superimposed on that of isovaleric acid (the standard molecule for the sweaty primary odour). The centres of gravity and the main axes of the silhouettes were co-aligned. The differences in the lengths of the thirty-six corresponding radii (broken lines) measured the difference in molecular size and shape between these compounds. If the average radial difference was \vec{L} , the molecular similarity was expressed by the reciprocal form $1/(\vec{L}+1)$.

The use of a greater number of A units gives a higher percentage of correct recognition, but this advantage should be balanced against the longer time required and the limiting memory capacity of the machine. The principle of scanning with random lines permits the solution of entirely different experimental problems from a highly generalized point of view, thus avoiding possible bias

through the use of preconceived scanning shapes. On the other hand, the accumulation of information by a threshold circuit allows the classification to be executed by a linearization process, and at the same time makes the features extracted in this way adequately invariant. Thus in experiments with alphanumeric characters, patterns of varying size or position are easily recognized, although the machine was instructed with patterns of fixed size and position.

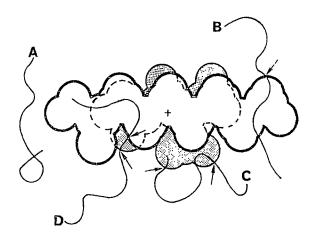

Fig. 2. The new PAPA intersection method. The machine scans each silhouette successively with the same collection of random lines, and counts intersections. For example, lines A and D each carry a similarity contribution, because A intersects neither silhouette and D intersects both silhouettes. Lines B and C each carry a dissimilarity contribution, for B intersects only one silhouette and C intersects only the other silhouette. Using 4096 random lines (A units) the machine computes probabilistically the molecular similarity in logarithmic form.

Although several different PAPA machines have been built with a variety of characteristics of performance, this experiment was performed with the most advanced design, now operating at the University of Genoa¹⁰. It may be thought of as a television camera linked to an electronic computer. It is a high-speed machine with a maximum recognition time of a few seconds, and can be arranged to view opaque patterns or transparencies. Its image-dissector camera, because of the non-storage properties of the tube, is very suitable for fast random scanning, while a computer unit with ferrite core memory rapidly accumulates the information. The answers are promptly printed out in the decimal number system, on a logarithmic probability scale with base 2.

Earlier PAPA machines have been successfully applied, for example, to recognize the rook and knight moves on a chessboard or to distinguish musical scores of J. S. Bach from those of an electronic composer¹¹. In recent months, to exploit the uncommon classificatory ability of the newest machine, some more practical problems have been presented, where the human visual system is quite unable to discern any pattern amidst a very large amount of data. For example, some preliminary experiments on weather prediction, directly from meteorological maps, have turned out to be very satisfactory.¹⁰

have turned out to be very satisfactory¹⁰.

The molecular silhouettes required by the present stereochemical problem, for displaying to the PAPA scanning camera, were prepared as follows. The scale molecular model (space filling type) was arranged in its most probable configuration and photographed in silhouette from three directions mutually at right angles². Rules of orientation were applied to ensure that the corresponding "top", "front" and "right" silhouettes of different molecular models represent comparable aspects. The positive prints were retouched with indian ink to fill any inter-atomic light chinks. The centre of gravity of the silhouette was found³ and marked by a small cross. The print was photographed again under dual electronic

flash with fixed geometry equipment and high contrast 35 mm film^2 . The negative film was mounted in 2×2 in cardboard projection slides, using a system of markers and templates to ensure accurate alignment. All numerals and markers were opaqued out on the film, except for the central cross, which is required for centring in the camera field of PAPA. The finished negative slides bear a single transparent molecular silhouette surrounded by a black background and have a scale of 0.14 cm/Å.

The selection of the optimal PAPA machine adjustments, for this particular problem, was approached by successive approximation, using a short series of fifteen molecular silhouettes obtained from a recent study of the odours of the aliphatic carboxylic acids. These compounds had earlier been shown to exhibit in varying degrees the primary odour of "sweatiness", depending on their resemblance in molecular size and shape to the standard primary odorant, isovaleric acid¹². The primary nature of this odour had been established by means of a group of persons specifically anosmic to (unable to smell) the sweaty odour. The degree of odour primacy of a given compound was estimated from the difference in its minimum detectable concentration between normal observers and specific anosmics. The molecular shapes had previously been measured by the manual radius method. The correlation coefficient then found between the manual measurements of molecular shape and the degree of odour primacy had been 0.75 (Fig. 3).

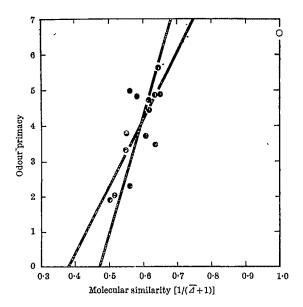

Fig. 3. Correlation between sweaty odour primacy among fifteen carboxylic acids and molecular shape similarity to isovaleric acid, measured by the manual radius method. The odour primacy scale is the log, of the threshold concentration ratio between specific anosmics and normal observers. (Two regression lines are shown because both variables are subject to experimental error; the open circle represents the isovaleric acid standard, which was omitted from the statistical analysis.)

Various settings of the PAPA machine were now tried, until the instrument became quantitatively responsive to the degrees of similarity between the molecular silhouettes. This was judged to have been accomplished when reasonably close agreement was reached between the instrumental measurements of molecular similarity and those obtained by the manual method. The top silhouettes only were used at this stage. Furthermore, only a single example silhouette was employed, that of isovaleric acid. In practice, the optimum performance by PAPA was achieved by appropriate adjustment of the average random line length, line curvature, threshold position and choice of comparative criterion.

The three values for the top, front and right silhouettes of each test compound were averaged to obtain the overall

molecular similarity between that compound and the standard compound, assessed by the PAPA intersection method. These molecular similarities were plotted against the same set of odour primacy values, previously obtained from the specific anosmia procedure. A correlation coefficient of 0.80 was achieved using the PAPA procedure (Fig. 4). This correlation coefficient by the PAPA intersection method was slightly better than by the manual radius method. It is interesting to note that the two scatter diagrams (Figs. 3 and 4) are almost identical; the correlation coefficient is 0.96 between the two measures of molecular similarity, manual and PAPA. The anomalous off-line position of the isovaleric acid standard itself in the radius method (introduced by the reciprocal term in the calculation) is avoided in the PAPA method.

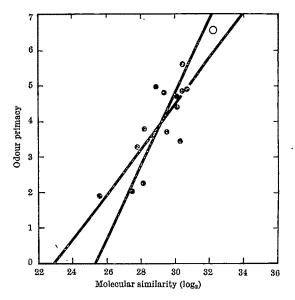

Fig. 4. The same odour primacy values as in Fig. 3, but plotted against molecular shape similarity measured by the PAPA intersection method. With slight adjustment of the horizontal scales, the points in Figs. 3 and 4 become almost superimposable. (The molecular similarity scale in \log_2 units gives relative values, not absolute.)

The same optimal machine settings which were effective for scanning the short series of fifteen carboxylic acids were now applied to review a long series of 107 compounds which also had been studied earlier¹³. In that survey not just one but five standard compounds were These were 1,2-dichloroethane; 1,8-cineole; employed. 15-hydroxypentadecanoic acid lactone; d, l- β -phenylethylmethylethyl carbinol; and d,l-menthone. represent, respectively, the ethereal, camphoraceous, musky, floral and minty classes of odour. (Note that these are merely classes of odour, and not proved primaries.) The similarities in odour quality between each of the 107 test odorants and each of the five standard odorants had previously been measured by means of a panel of normal observers, using a matching standards procedure¹⁴. In this method the judges compare the unknown with the standard odour, and rate the degree of similarity on an intuitive scale from 0 to 8.

The PAPA instrument can handle up to sixteen example classes simultaneously, and so the machine was instructed with the top silhouettes of all five standard compounds (one example only for each class). To avoid over-filling the machine's memory, the number of A units was reduced from 4,096 to 1,024. In response to each test top silhouette, the instrument printed out five values, representing the individual similarities of the test silhouette to each of the five standard silhouettes. Then all the memory circuits of PAPA were cleared, and the process was repeated for the front and right silhouettes.

Correlation coefficients were calculated between these molecular similarities obtained from the PAPA intersection method and the corresponding odour similarities measured by the matching standards procedure¹⁴. The results for the five classes of odour are shown in Table 1, together with the known correlation coefficients¹³ between the same odour values and the manual radius method of measuring molecular shape. In the camphoraceous and floral classes there was a small improvement in the correlation coefficient with the new PAPA method for assessing molecular shape. The ethereal class was unaffected, but the musky and minty classes showed a rather less satisfactory correlation, largely because of a slight bias in favour of the manual radius method contributed by the reciprocal term. Nevertheless, the changes do not materially affect the earlier conclusion 13 that there is a highly significant correlation between odour quality and molecular shape ($P < 10^{-9}$ for each class of odour).

Table 1. COMPARISON OF THE MANUAL RADIUS AND PAPA INTERSECTION METHODS FOR MEASURING THE MOLECULAR SILHOUETTES OF 107 ODOROUS COMPOUNDS

	Correlatio	n coefficient
Odour	Manual	PAPA
Ethereal	0.66	0.66
Camphoraceous	0.56	0.58
Musky	0.62	0.53
Floral	0.54	0.58
Minty	0.52	0.45

The two sets of molecular shape measurements were correlated with the same set of odour similarity measurements¹³. Results are given for five classes of odour.

Evidently, the PAPA machine can be considered to supersede the manual method for comparing molecular silhouettes, whenever more than a few compounds are to be studied, on account of its hundred times greater speed. Extensive tests have so far been made with only one method of scanning the silhouettes, the intersection method. Preliminary trials with the area method on the fifteen carboxylic acids gave an even higher correlation coefficient of 0.84. It is encouraging to find that more than 70 per cent of the variance in the sweaty odours of these acids can be explained simply with three photographs of a conventional molecular model.

The PAPA pattern recognition machine has much greater associative and inductive power than has yet been

applied to the problem of the molecular silhouettes. For example, instead of exhibiting just one standard compound with a particular odour, one could show to the machine many examples of compounds having the same odour, and let the machine develop its own criteria for distinguishing compounds possessing the odour. definitive information becomes available from the specific anosmia procedure on the identities and stereochemical characteristics of the primary odours12, the PAPA machine is expected to become increasingly useful for estimating theoretically the contribution towards each primary that can be expected from a newly identified odorant, or even from a projected synthesis.

Although the present application of the PAPA pattern recognition machine to the molecular morphology of chemicals has been exclusively with regard to their odours, it seems reasonable to suppose that similar principles should apply for other chemical-constitution/biological activity relationships. The highest activities of drugs, pheromones and pesticides usually require, among other things, optimization of molecular shape. A PAPA machine with enlarged memory, capable of conducting a massive screening of known chemical compounds against desired biological activities, might help reveal many valuable products lying dormant in the literature.

We thank Professor A. Borsellino for suggesting this collaboration, Professor A. Gamba for helpful discussion and Paul Kayfetz for special photography. The PAPA machine used in this experiment was built with the support of Consiglio Nazionale delle Ricerche through the Gruppo Nazionale Cibernetica.

Regulation of Cytochrome Oxidase in Human Cells in Culture

N. HAKAMI D. A. PIOUS

Department of Pediatrics, School of Medicine, University of Washington, Seattle, Washington

The range of adaptation of the terminal respiratory apparatus in response to environmental variation is considerably less for human cells than for yeast cells. In addition, availability of oxygen in human cells regulates the content of cytochrome oxidase rather than its activity.

THE regulation of the formation of mitochondria and of mitochondrial enzyme synthesis has been extensively studied in lower organisms but not in the cells of higher organisms. In yeast, for example, the synthesis of cytochromes and the formation of mitochondria are markedly repressed by anaerobiosis, and also by a high concentration of glucose in the growth medium1-4. For human cells, cell

culture affords a unique opportunity to evaluate mechanisms of regulation of cellular respiratory enzymes. Such studies are interesting because of the possibility that the control mechanisms are basically different from those of lower organisms, and also because of the possible relevance of regulation of cellular respiratory enzymes to human pathophysiology.

We report here studies of the regulation of activity of the terminal component of the electron transport chain, cytochrome oxidase, in cultured human cells. These findings have been correlated with cytological observations of mitochondria in conditions in which cytochrome oxidase is, and is not, induced. Both similarities and differences between human cells and those of lower organisms with respect to regulation of cytochromes and of the development of mitochondria have been revealed.

Cultures of fibroblasts from the foreskins of newborn humans were initiated and maintained by methods which have been described before. The growth medium for all experiments was medium 199 with 15 per cent foetal bovine serum. Aerobically grown cultures were flushed with 97 per cent air and 3 per cent carbon dioxide and were then sealed and incubated at 37° C. Anaerobically grown cultures were treated similarly except that there was

nitrogen instead of air in the gas mixture.

To estimate enzyme activity, monolayer cultures were suspended by trypsinization and trypsin was removed by centrifugation. Cells were disrupted by adding to the pellet cold 1 per cent deoxycholate in 0.013 molar phosphate buffer, pH 7.4. Disruption of cells in this way occurred immediately on mild agitation and pipetting. Assay for cytochrome oxidase was performed by following spectrophotometrically the oxidation of reduced cytochrome cafter the addition of the cell lysate. In addition to the cell lysate, the reaction mixture contained at the final concentrations, 1 per cent (w/v) reduced cytochrome c, 3 per cent (w/v) deoxycholate and 0.013 molar phosphate buffer, pH 7.4. The specific activity was calculated using the

extinction coefficient $\Delta_{EmM\, red. - ox = 19\cdot 1}$ for cytochrome c^6 . For preparation of mitochondria, cultures of fibroblasts were collected by trypsinization. The cells were suspended in 0.013 molar phosphate buffer containing 0.25 molar sucrose and were sonicated for 4 min, which resulted in disruption of 80-95 per cent of cells as determined by microscopic examination. (Sonication for longer than 4 min resulted in disruption of 100 per cent of cells, but diminished the enzyme specific activity.) The sonicate was centrifuged at 1,000g for 10 min. The pellet (P₁) consisted of nuclei, cell debris and the remaining undisrupted cells. The supernatant (S_1) was centrifuged at 10,000g for 10 min, giving a mitochondrial pellet (P2) and a supernatant (S_2) .

Protein was measured by the method of Lowry et al.7. Glucose was assayed enzymatically with glucose oxidase, using orthotolidin as oxygen acceptor⁸.

Table 1. OYTOCHROME OXIDASE ACTIVITY OF HUMAN ORLLS GROWN IN THE PRESENCE AND ABSENCE OF OXYGEN

Experi-	Cell	Duration	Cytochrome oxidase activity* Aerobic			
ment	type	of growth (days)	Aerobic growth	Anaerobic growth	growth, then anaerobic growth	
1 2 3 4 5 6 1-8 (mean ± SEM)	Fibroblasts	6 9 10 20 10 13	5·8 3·8 4·7 3·1 7·2 9·0 5·6 ± 0·9	1.0 0.8 2.5 0.8 2.2 1.3 1.4 ± 0.3	4·8 4·5	
7 8	HeLa	6 10	11·0 12·0	4·7 3·0		

^{*} μmoles of substrate oxidized/mg protein/min.

Aerobically grown cultures were grown in 97 per cent air-3 per cent CO_* ; anaerobically grown cultures were grown in 97 per cent N_* -3 per cent CO_* . Following the growth periods indicated, cytochrome oxidase assays were performed on cells lysed with deoxycholate.

Studies of the effect of anaerobic growth for one or two passages (five to ten cell generations) on cytochrome oxidase activity revealed consistently less activity in these cells than on controls grown aerobically (Table 1). In six experiments, the activity of cytochrome oxidase in lysates of cells which were aerobically grown was $5.6 \pm 0.9 \mu \text{moles}$ of substrate oxidized/mg of protein/min, compared with a

mean of 1.4 ± 0.3 for cells grown anaerobically. difference between the two means is significant at the level of P < 0.01. Comparisons of enzyme activity in aerobically and anaerobically grown HeLa cells revealed a similar phenomenon. Although the level of enzyme activity in HeLa cultures grown aerobically was higher than that of fibroblasts, HeLa cultures grown anaerobically had significantly lower activity than aerobically grown HeLa cultures, with means of 3.8 and 11.5, respectively.

In addition to its effect on cytochrome oxidase activity, anaerobiosis in fibroblasts resulted in a reduction of approximately 40 per cent in the yield of cells and of protein compared with that of aerobically grown control cultures. This difference in growth was also evident from a comparison of average generation times of aerobically and anaerobically grown fibroblasts which were 29 h and 41 h, respectively. Fibroblasts could be grown anaerobically for at least five passages without further change in growth parameters; HeLa cells, on the other hand, failed to survive in anaerobic conditions for longer than 6-7 days.

One possible explanation of the reduced enzyme activity of anaerobically grown cells is that anaerobiosis selected variants within the cell population which were heritably deficient in enzyme. If this were the case, restoration of anaerobically grown cells to aerobic growth would not result in recovery of cytochrome oxidase activity to levels characteristic of aerobically grown cells. As can be seen from experiments 3 and 4 of Table 1, however, when anaerobically grown cells with reduced cytochrome oxidase activity (activities of 2.5 and 0.8, respectively) were grown for one passage in air, activities characteristic of aerobic growth (4.8 and 4.5) were regained. The fact that the anaerobic effect was reversible makes it unlikely that anaerobiosis selected for cells with low enzyme activity.

Another means by which anaerobic growth might lead to reduction in cytochrome oxidase activity is by inducing synthesis of an inhibitor of enzyme activity. The presence of an inhibitor was sought by determining whether the enzyme activity of mixtures of deoxycholate lysates of aerobically and anaerobically grown cells was significantly lower than the mean of the component activities assayed independently. In such a mixing experiment (Table 2), no evidence for the presence of an inhibitor was found. The specific activity of aerobically grown cells was 5.9, that of anaerobically grown cells 1.3, and that of a 1:1 mixture of the two was 3.5.

Table 2. Enzyme Activity of Mixed Lysates of Aerobically and Anaerobically grown cells

Cell extract Sp	ecific activity
Aerobic growth	5-9
Anaerobic growth	1.3
1:1 mixture of aerobic and anaerobic growth	3.5

* μ moles substrate oxidized/mg protein/min.

Deoxycholate lysates were prepared from aerobically and anaerobically grown fibroblast cultures. Cytochrome oxidase activity was assayed in each lysate and in a 1:1 mixture of the two lysates.

A further possible mechanism of inhibition of cytochrome oxidase activity in anaerobically grown cells is that lack of oxygen caused conformational changes in the enzyme molecule which rendered it inactive. If this were the case, enzyme inactivated by anaerobic growth might be reactivated by in vitro exposure to oxygen and, conversely, active enzyme from aerobically grown cells might be inactivated by deprivation of oxygen in vitro. investigate this possibility, mitochondria were isolated from aerobically and anaerobically grown cells, then incubated with oxygen and nitrogen and the effect of this incubation on the enzyme activity was determined.

The distribution of cytochrome oxidase activity in different fractions of an aerobically grown fibroblast preparation is shown in Table 3. The bulk of the activity was present in P_2 , the 10,000g pellet. The activity in P_1 (approximately 6 per cent) is believed to be accounted for by cells which were not disrupted by sonication but which were lysed by subsequent exposure to deoxycholate. Of the remaining activity, over 98 per cent was sedimented at 10,000g, a force known to sediment mitochondria. Mitochondria were isolated from fibroblasts grown in air or in nitrogen for 10 days. Cytochrome oxidase assay was carried out on a portion of each mitochondrial preparation. The remaining portion of mitochondrial preparation from the culture which had been grown in nitrogen was suspended in phosphate buffer, through which air had been vigorously bubbled for 10 min. After suspension in buffer, the supernatant gas was continuously flushed with air for 5 min and cytochrome oxidase activity was measured. A portion of the mitochondrial preparation from cells grown in oxygen was suspended in buffer through which nitrogen had been bubbled for 10 min; the supernatant gas was flushed with nitrogen for 5 min and enzyme assay was carried out.

Table 3. DISTRIBUTION OF CYTOCHROME OXIDASE ACTIVITY IN MITOCHON-DRIAL AND NON-MITOCHONDRIAL CELL FRACTIONS

Fraction	Total	Total	Percentage	Percentage
	protein (mg)	activity*	total protein	total activity
P ₁ P ₂ S ₂	7·22	39	42	6·3
	2·16	564	12·6	92·0
S.	7.7	10	45.4	1.7

* µmoles substrate oxidized/min. Fibroblasts were disrupted by sonication for 4 min, then centrifuged at 1,000g for 10 min. The 1,000g pellet (P_1) , which consisted of cell fragments, nuclei and undisrupted cells (approximately 15 per cent of the total cells initially present), was dissolved in 1 per cent deoxycholate. The 1,000g supernatant was centrifuged at 10,000g for 10 min, giving a pellet (P_1) and a supernatant (S_2) . The pellet was resuspended in 0-013 molar phosphate buffer containing 0-25 molar sucrose. Cytochrome oxidase assays were performed on P_1 , P_2 and S_2 .

The results of this experiment are shown in Table 4. For the mitochondrial preparations not treated in vitro, the preparation from aerobically grown cells was four times as active as that from anaerobically grown cells (specific activities of 150 and 35, respectively). In vitro incubation of mitochondria from anaerobically grown cells in buffer saturated with air did not affect a rise in activity (preincubation specific activity 28·0). Similarly, incubation of mitochondria from aerobically grown cultures in buffer saturated with nitrogen did not reduce cytochrome oxidase activity (preincubation specific activity 150, post-incubation specific

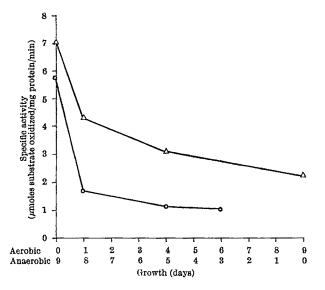

Fig. 1. Kinetics of loss of cytochrome oxidase activity of cultures transferred from aerobic to anaerobic growth. Groups of cultures were grown for 0, 3, 5, 8 or 9 days aerobically and were then transferred to anaerobic growth for the remainder of a 9 day growth period, at which time cytochrome oxidase assay was performed. The curves are from separate experiments.

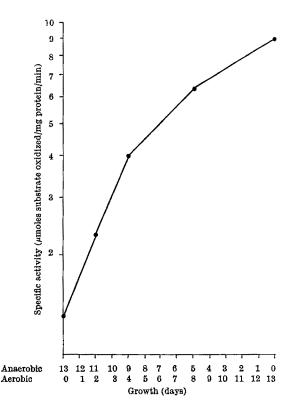

Fig. 2. Kinetics of gain of cytochrome oxidase activity of cultures transferred from anaerobic to aerobic growth. Groups of cultures were grown for 0, 4, 9, 11 or 13 days anaerobically, then transferred to aerobic growth for the remainder of a 13 day growth period, at which time cytochrome oxidase assay was performed.

activity 190). These data make it unlikely that growth in an altered gas environment resulted either in conformational or other alterations of enzyme molecule which rendered it inactive. Although in vitro incubation experiments cannot exclude conformation or other molecular changes dependent on an in vivo process, the implication of the in vitro experiments is that change in enzyme content, rather than alteration in pre-existing enzyme molecules, is involved in variation in enzyme activity resulting from variation in oxygen environment.

Table 4. EFFECT ON ACTIVITY OF BUBBLING OXYGEN AND NITROGEN THROUGH MITOCHONDRIAL PREPARATIONS

Growth condition	Treatment of mito- chondrial preparation	Activity of mito- chondrial preparation*
Aerobic	None Bubbled with nitrogen	150 190
Anaerobic	None Bubbled with oxygen	35 28

^{* \}mu moles substrate oxidized/mg protein/min.

Mitochondria were prepared from cells which had been grown aerobically and anaerobically as described in Table 1. Treatment consisted of bubbling the suspending buffer with the designated gas for 10 min, suspending the preparation in the bubbled buffer, and flushing the supernatant gas layer with the gas for 5 min. Control preparations were suspended in untreated buffer and were not flushed.

The mechanism of the anaerobic effect was further investigated by studies of the kinetics of loss of activity on transfer from aerobic to anaerobic growth, and of its regain when the transfer was reversed. It can be seen from Fig. 1 that activity decreased rapidly during the first 24 h after transfer from aerobic to anaerobic conditions. In two experiments, the loss in activity during the first 24 h was 40 per cent and 70 per cent of aerobic values, respectively. Based on an observed average generation time of 41 h for anaerobic cultures, the loss expected, if the mechanism of the anaerobic effect was to stop the synthesis of mitochondria and dilute pre-existing mitochondria by cell division, would be of the order of 30 per cent

 $\left(\frac{24}{41} \times 50 \text{ per cent}\right)$. It therefore seemed unlikely that the anaerobic effect on cytochrome oxidase was a function of cessation of synthesis of mitochondria. That the synthesis of mitochondria as such was not involved was also indicated by cytological studies.

When cells changed from anaerobic to aerobic growth the gain of enzyme activity proceeded exponentially during the first 4 days and then more slowly (Fig. 2). Within the limits of the experimental points obtained, there seemed to be no initial lag before the increase in activity following the transfer, suggesting that all components required for synthesis of enzymes were present at the time of transfer. This finding is under continued study.

activity in human cells was found to be reduced after anaerobic growth, genesis of mitochondria itself appeared unaffected. The more limited responses of human cells seem consistent with the more limited adaptive demands of cells the external environment of which is controlled (human) as opposed to uncontrolled (yeast). Human cells grown anaerobically did, however, have significantly lower cytochrome oxidase activity than aerobically grown These findings are consistent with those of controls. previous studies indicating decreased cellular respiration in anaerobically grown cells^{10,11}. That the availability of oxygen regulates the cellular content of cytochrome oxidase rather than its activity is indicated by the lack of effect on activity, of incubation of mitochondria in 100 per

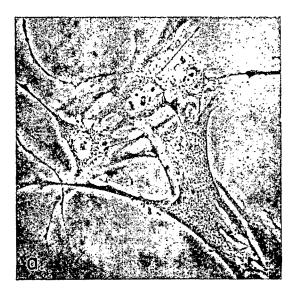

Fig. 3. Phase contrast photomicrographs of aerobically and anaerobically grown cells (×320). a, Aerobically grown cells; b, anaerobically grown cells. Abundant numbers of mitochondria are visible in each.

Cytological observations were made to determine whether anaerobically grown cells with reduced cytochrome oxidase activity had an associated reduction in the number of mitochondria in each cell. A comparison of aerobically and anaerobically grown cells by phase contrast microscopy (Fig. 3) did not reveal, however, any gross difference in the number of mitochondria which paralleled the differences in enzyme activity. This is in contrast to the findings for yeast, when cells grown anaerobically have fewer mitochondria or none at all3. It is of interest that a concentrated glucose medium, which strongly represses cytochrome synthesis in yeast4, had no effect on cytochrome oxidase of human cells. Cells were grown for 12 days in media containing a range of concentrations of glucose from 0.001 to 1.4 molar (normal growth medium contains 0.06 molar glucose). In the "high glucose" cultures, the glucose concentration was maintained by periodic medium changes. At the highest concentration of glucose used, growth was markedly reduced. At the lowest concentration of glucose used, glucose was not detectable in the medium at the time of assay. At no concentration of glucose, however, did the specific activity vary significantly from that of cells grown in the standard growth medium.

From the present studies, it seems that the range of adaptation of the terminal respiratory apparatus in response to environmental variation is considerably less for human cells than for yeast cells. Pertinent findings from the present studies in this respect are the insensitivity of human cells to repression of cytochrome synthesis by high glucose. In addition, although cytochrome oxidase cent oxygen or nitrogen in vitro (Table 4). Whether oxygen regulates the rate of cytochrome oxidase synthesis or of its degradation in vivo is not yet known. It will also be of interest to determine whether the regulation of cytochrome oxidase by oxygen plays a part in the pathophysiology of human hypoxic states; this depends, in part, on whether the level of cytochrome oxidase activity is a rate limiting step in respiration in human cells.

LETTERS TO THE EDITOR

ASTRONOMY

Do Radio Stars Exist?

Wherick and Véron¹ have suggested that there is a new class of radio objects—namely, radio stars. This suggestion was based on a search in the positions of 3C (revised) radio sources having $|b^{\rm II}| > 30^{\circ}$ for which no identification with an optical object had been made. The search led to the discovery of apparent coincidences between the positions of seven radio sources and those of objects with normal stellar spectra and $m_v \leq 20$.

The positions of these sources have been determined with improved accuracy using the one-mile telescope² of the Mullard Radio Astronomy Observatory at a frequency of 1,407 MHz.

Table 1 gives the new positions together with their probable errors; it also gives the difference between these positions and the optical positions quoted by Wlerick and Véron, which have an accuracy of about ± 1 " are in each co-ordinate. Two of the sources are unresolved by the 23" are beam and only upper limits can be placed on their angular dimensions. Three of them are partially resolved, and the half-power widths of Gaussian source models, which fit the observations along particular position angles, are given in the table; the remaining two are well resolved double sources. This distribution of angular structure is very similar to that found in a large sample of 3C sources, most of which are identified with extragalactic Although it is only possible to guess at the physical mechanisms which might operate in a new type of galactic radio source of stellar dimensions, it would be remarkable if they gave rise to radio components with an angular structure so similar to that associated with extragalactic sources of similar flux density.

Sketch maps of the two double radio sources are shown in Fig. 1; the object suggested as being related to 3C 356 lies some $6'' \cdot 5 \pm 3'' \cdot 5$ off the radio axis³ while that suggested for 3C 435 is very close to the radio axis. It is well known that in the case of extensive double sources, it is difficult to establish conclusive identifications because of the large area in which a related object might lie; in the case of 3C 435, it is probable that, if the object mentioned by Wlerick and Véron had been a galaxy, previous authors would have regarded it as a good identification.

For the five compact sources, the positional discrepancies do not, in most cases, exceed the combined errors by a large factor. Nevertheless, it can be shown that the associations may probably be attributed to

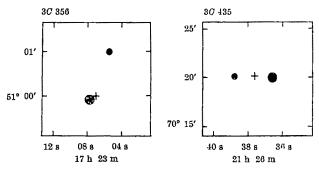

Fig. 1. Positions of the radio peaks (•) and the optical objects (+) mentioned in ref. 1, for the two well extended double sources. The larger spot in each region indicates the brighter component.

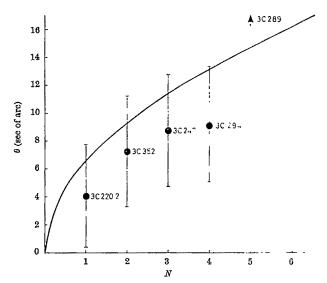

Fig. 2. N, The number of stars expected within an angular distance θ of the radio brightness peak over forty-six fields with $|\delta u| > 30^\circ$. The discrepancies between the radio positions and the optical positions given by Wlerick and Véron are also plotted for the five compact sources.

chance. As Wlerick and Véron have pointed out, it is difficult to make an estimate of the star density likely to occur in any given field. Data from another programme were, however, available which allowed the determination of the star density in areas covering the same ranges of galactic latitude and longitude as those examined by Wlerick and Véron. A count was made in each of fortyone areas $4'.5 \times 4'.5$ are in extent of the number of starlike objects with apparent photographic magnitude, $m_{\rm pg}$, ≤ 20 . An average of twelve stars was found in each region, with a standard deviation of six. If these areas can be regarded as having an average stellar population similar to those of the forty-six 3C fields with $|b^{\rm II}| > 30^{\circ}$ which were noted as "blank" by Wyndham⁴.

		Table 1	
	Radio position beginning of 1950	Position difference (radio minus optical)	Structure
3C 220·2	$\begin{array}{cccccccccccccccccccccccccccccccccccc$	$\begin{array}{ccc} -0.3 \text{ s} & \pm 0.23 \text{ s} \\ 0.1'' & \pm 3'' \end{array}$	<17" at position angle 0 <10" at position angle 90

3C 289	13 h 43 m 27.6 s ±0.2 s 50° 01′ 31.4″ ±2″	-1·2 s ±0·3 s 25·3" ±3"	~10" at position angle 110° <10" at position angle 20°
3C 294	14 h 04 m 33.95 s ± 0.15 s 34° 25′ 39.5″ ± 2″	$\begin{array}{cccccccccccccccccccccccccccccccccccc$	~10" at position angle 20 ~10" at position angle 31" <10" at position angle 121°
3C 352	$\begin{array}{cccccccccccccccccccccccccccccccccccc$	$\begin{array}{cccc} -0.25 & \pm & 0.3 & 8 \\ -0.7'' & \pm & 3'' \end{array}$	<14" at position angle 77°
3C 356	17 h 23 m 05·53 s ±0·3 s 51° 00′ 59·0″ ±3″ 17 h 23 m 07·87 s ±0·3 s 50° 59′ 54·1″ ±3″	$\begin{array}{cccc} -0.768 & \pm 0.48 \\ -0.168 & \pm 0.48 \\ 59.1'' & \pm 4'' \\ 0.188 & \pm 0.48 \\ -5.8'' & \pm 4''' \end{array}$	<10" at position angle 77° 69" are double at position angle 161°
3C 435	$\begin{array}{cccccccccccccccccccccccccccccccccccc$	$\begin{array}{cccccccccccccccccccccccccccccccccccc$	30" arc double at position angle 83°

then it is possible to calculate the number of sources in this sample, which would lie at a given separation from stars having $m_{\rm pg} \le 20$. The results are plotted in Fig. 2, together with the actual separations between the radio and optical positions for the five compact sources. It can be seen that, even with the fairly small positional discrepancies given in Table 1, the number of associations is no more than can be attributed to chance.

It must therefore be concluded that while it will never be possible to exclude the hypothesis that certain radio sources are identified with galactic stars, there is now no evidence to support it. The more accurate radio positions for these seven sources do not, however, enable any alternative identifications to be made with other objects visible on the Sky Survey Prints.

Absorption Lines in Quasi-stellar Objects

GAMOW1 has attempted to explain the lack of correlation between apparent brightness and red-shift of quasi-stellar objects2,3 as being caused by the fact that the red-shifts are measured from absorption spectra which he has argued are caused by galaxies intercepting the light from more distant quasti-stellar objects. In this case, no correlations could reasonably be expected because the apparent magnitude would refer to one object and the red-shift to another.

Gamow's conclusion, however, is based on a misinterpretation of the observational data. All the red-shifts which have been used in the analysis by Longair and Scheuer³ are emission-line red-shifts^{4,5} which cannot arise in anything other than the quasi-stellar object itself.

It is true that some quasi-stellar objects do have absorption lines in their spectra in addition to the emission lines, and we have summarized all the data now available on the red-shifts of the absorption lines. Only about twenty quasi-stellar objects out of the 104 with known red-shifts do in fact show absorption features. absorption-line red-shifts, z_{abs} , are found either to be approximately equal to the emission-line red-shifts, $z_{\rm em}$, or to have a "standard" value of about 1.95. In cases where $z_{abs} \approx z_{em}$ there is no question but that the emission lines and the absorption lines all arise in the quasi-stellar object. In cases where $z_{abs} \approx 1.95$, often $z_{em} > z_{abs}$, or $z_{\rm em} \approx z_{\rm abs}$, but there is at least one case where $z_{\rm abs} > z_{\rm em}$ by a small amount. Spectroscopic arguments^{7,8} strongly suggest that in these cases, also, the regions producing the absorption lines are very close to the source of radiation in the quasi-stellar object. This, together with the fact that a "standard" red-shift seems to have been found, led us to the conclusion that these red-shifts are largely intrinsic and not cosmological. Shklovsky, however, has argued that the "standard" absorption spectrum, zabs ≈ 1.95 , is caused by galaxies all at this (cosmological) red-shift, an idea which forces one to the conclusion that a cosmological model of the Lemaitre type is required. But in no case do the data support the idea that the absorption is taking place in galaxies with a wide range of red-shifts.

Emission of [O II] and [O III] Forbidden Transitions by Quasi-stellar Objects

THE observation of forbidden transitions in the emission spectra of quasi-stellar objects1,2 has led previous authors to deduce limiting values for the electron density in relevant regions of these sources (for example, ref. 1). In this report I shall show that significant limits must be set on the ultraviolet radiation intensity in the emitting region, and thus on the size of the region, if the observations of certain [O II] transitions are to be explained even at low electron densities.

The level scheme relevant to both O II and O III is shown in Fig. 1. I consider the alteration in the forbidden line intensities produced by photoexcitation to levels connected by allowed transitions to both the metastable states, 1 and 2. For simplicity, only the nearest such excited level, 3, is considered. The collisional depopulation of levels 1 and 2 is neglected in comparison with radiative processes, because my interest is in conditions where forbidden transitions are emitted strongly. Spontaneous radiative transitions are assumed to be the only significant processes depopulating level 3. excitation to levels connected to a single metastable leve by allowed transitions can be ignored, because the eventual return of the electron to the original level implies that the forbidden line intensity is unchanged. Levels 1 and 2 are also populated at rates P_1 and P_2 by processes other than photoexcitation from either level and subsequent decay—the rates P_1 and P_2 need not be specified in detail in what follows, and may include either collisional excitation or radiative cascade. The ratio of the inten-

Allowed transitions; - - - . forbidden Fig. 1. Level scheme. transitions.

sities of any two of the forbidden transitions is then easily obtained from the rate equations for the populations of levels 1 and 2. Thus the relative rate of emission of photons is

$$\frac{n_1 A_{10}}{n_2 A_{20}} = \frac{C + \frac{P_1 + P_2}{P_2} \frac{\Gamma_1 I_{32} B_{23}}{A_{20}}}{1 + \frac{P_1 + P_2}{P_2} \frac{\Gamma_2 I_{31} B_{13}}{A_{10}}}$$
(1)

where C, the same ratio but in the absence of the radiation field. is given by

$$C = \frac{P_1(A_{21} + A_{20})}{P_2 A_{20}} \tag{2}$$

Here $A_{\rm nm}$ is the spontaneous transition probability, $B_{\rm mn}$ is the Milne coefficient (the absorption transition probability in terms of the intensity) of the n-m transition and $I_{\rm nm}$ is the radiation intensity at the relevant frequency. Γ_1 and Γ_2 are the branching ratios from level 3

$$\Gamma_1 = \frac{A_{31}}{A_{31} + A_{32}}, \quad \Gamma_2 = \frac{A_{32}}{A_{31} + A_{32}}, \quad \Gamma_1 + \Gamma_2 = 1$$
 (3)

Suitable values for the transition probabilities are tabulated by Wiese³, the important values A_{20} , A_{21} and A_{10} for O II being those of Seaton and Osterbrock⁴, namely $4\cdot7\times10^{-2}$ sec⁻¹, $1\cdot7\times10^{-1}$ sec⁻¹, and 9×10^{-5} sec⁻¹ (averaged values). The $\lambda3727$ Å [O II] ${}^4S^{-2}D$ (0–1 in my notation) line usually would be expected to be considerably stronger than $\lambda2470$ Å [O II] ${}^4S^{-2}P$ (0–2) in the absence of a radiation field, both because the ratio of P_1 to P_2 is large if the excitation is collisional⁵, and also (regardless of the excitation mechanism) because of the high (relative) value of A_{31} . At first sight therefore the failure to observe $\lambda2470$ Å in those quasi-stellar objects with both sufficient red-shift and strong $\lambda3727$ Å emission is not surprising.

If, however, $A_{10} \ll A_{20}$, and (as occurs in practice) the ratios of B_{13} to B_{23} , I_{31} to I_{32} and Γ_1 to Γ_2 do not differ greatly from unity, the ratio of intensities of $\lambda 3727$ Å and $\lambda 2470$ Å will be greatly reduced if the radiation intensity exceeds a critical value, and will ultimately approach a limit of the order of the ratio of the transition probabilities, that is approximately 10^{-2} . Values for B_{13} , B_{23} , Γ_1 and Γ_2 can be obtained from ref. 3. Γ_2 will depend on the exact number of excited levels considered, and for O II may vary from 0.125 to 0.5, but a suitable value when including only the $2s2p^4$ 2D level is 0.125. The cross-sections given by Aller⁵ suggest that this is about compensated by the $(P_1 + P_2)/P_2$ factor in the denominator if the excitation is collisional, and in the case of radiative cascade this compensation would be exact. It can therefore be concluded that in either case the critical intensity is given by

$$I_{31}(\lambda = 718 \text{ Å}) = \frac{A_{10}}{B_{13}} = \frac{2hv_{31}^8}{c^2} \frac{g_1}{g_3} \frac{A_{10}}{A_{31}} = 3 \times 10^{-14}$$
ergs cm⁻² sec⁻¹ (c/s)⁻¹ steradian⁻¹

This intensity is orders of magnitude smaller than that expected from several predictions (for example, refs. 1, 2 and 6) of the total ultraviolet flux and of the dimensions of the emitting region and so we can draw some interesting conclusions about those sources for which [O II] $\lambda 3727$ Å is observed (for example, 3C 249, 3C 277, 3C 48 but not 3C 273). Wampler and Oke⁶ adopt an ultraviolet continuum flux of 8×10^{29} ergs sec⁻¹ (c/s)⁻¹ and a radius of 10^{18} cm. With their value for the total flux, however, the minimum radius of the [O II] region if the critical intensity given here is not to be exceeded is

$$R > 4 \times 10^{20} \text{ cm}$$

Even assuming an intensity in the emitting region greater than the critical value by a factor of ten, the minimum radius still exceeds previous estimates by two orders of magnitude. Burbidge $et\ al.^2$ have proposed on other grounds that the forbidden transitions will be emitted in the outer layer of the source. With the parameters of their so-called region II ($T_c=3$ eV, $N_s=10^8$ cm⁻³, $R=10^{18}$ cm) the continuum flux at 718 Å due to bremstrahlung and Lyman recombination radiation is 4×10^{31} ergs sec⁻¹ (c/s)⁻¹. The minimum radius for the [O II] emitting region is then

$$R > 2.9 \times 10^{21} \text{ cm} = 10^3 \text{ parsec}$$

This radius is theoretically resolvable at the distance estimated for those quasi-stellar objects with relatively small red-shifts. Other problems are raised by so large an [O II] region. For example, Burbidge et al.² ascribe the widths of forbidden lines to electron scattering, which is consistent with their predictions on other grounds of a radius of 10¹⁸ cm and an electron density exceeding 10⁸ cm⁻³. The scattering hypothesis, however, would still require an electron density of 10⁴ cm⁻³ at the radius of 10²⁰ cm estimated here as the minimum for the [O II] region, that is an increase of four orders of magnitude in the total number of electrons in the source.

The [O III] lines are less restrictive because A_{10} is larger, but are still interesting as both $\lambda5007$ Å $^3P^{-1}D$ (0-1) and $\lambda4363$ Å $^1D^{-1}S$ (1-2) transitions are seen in some sources, the former being the stronger and the more frequently observed. Again this is, as expected in the absence of a high ultraviolet intensity, $\lambda5007$ Å, being some two orders of magnitude the stronger in planetary nebulae. Because, however, the transition probabilities differ by a factor of 80, a high ultraviolet intensity should alter the intensity ratio until $\lambda4363$ Å is much the stronger. Because A_{10} is about 2×10^{-2} sec⁻¹ the critical intensity is two hundred times larger than for [O II], that is the minimum radii are about fourteen times smaller than given here, but still an order of magnitude larger than previous estimates.

The absence of [O III] $\lambda 3727$ Å and the relative weakness of [O III] $\lambda 5007$ Å were the grounds on which Greenstein and Schmidt¹ proposed a high electron density for 3C 273. Because in this case the red-shift is too small for $\lambda 2470$ Å to be observed, a possible alternative explanation is a high radiation intensity in the emitting region and the postulate of high density and its consequences should be re-examined.

This preliminary study can necessarily yield only somewhat general conclusions. Some features at least of existing models of quasi-stellar objects need re-examining, because the predicted ultraviolet fluxes would require the regions emitting forbidden lines to be much further from the central object than previously realized. The inclusion of the many other possible levels to which photoexcitation can occur (for example, the $2p^2$ 3s and 3d configurations in O II) would increase the distances still further, and would be particularly significant for those models postulating high central temperatures, and thus a slow decrease of the ultraviolet flux with frequency. Obviously many exceptions can be taken to the estimates of the ultraviolet flux, but equally other properties of the models then need reconsideration. Estimates of the maximum size of the [O II] regions from fluctuation data would be particularly interesting, although Oke^7 has already shown that in 3C 279 and 3C 446 emission lines do not seem to vary with the continuum. Because data on the maximum size of such regions combined with observations of the relative intensities of forbidden lines can set significant upper limits on the absolute ultraviolet flux from quasi-stellar objects, the most interesting conclusion is perhaps that there exists in principle at

least a means of estimating upper bounds to the distance of such sources independently of their red-shifts.

PLANETARY SCIENCE

Water on the Moon

THE possibility that water has existed on the Moon for varying lengths of time, both in liquid and in solid form, and both beneath the surface and on the surface, has been widely discussed during the past 10 years¹⁻⁷. The subject has been discussed repeatedly at scientific meetings and has been received mostly with great scepticism. Evidence supporting this view has recently become quite overwhelming and, in fact, no communication seems necessary to point out the evidence from the Orbiter 4 and 5 pictures. Because many people are not aware of this evidence and suggest that the effects are caused by other liquids, that is, lava, dust-gas or possibly even vodka, a brief discussion of the evidence may be in order.

Gold's pointed out that it was unreasonable to believe that all the smooth areas within the craters and between the craters were caused by lava flowing from deep in the Moon, and he suggested that dust produced by particle erosion was the origin of the material filling these craters and the maria. Because of the lack of dust river valleys, I disagreed with this and suggested that dust from the great collisions and temporary rains washed the dust into the low areas, and the water escaped into space or sank below the surface. Gilvarry⁵ postulated much more extensive oceans lasting for billions of years. Although many of Gilvarry's observations are reasonable, the long length of time assumed, with no evidence for mature river valleys, unfortunately led to definite non-acceptance of his ideas. Gold' and Kopal' have suggested that water has escaped from the lunar interior and formed permafrost similar to that found in the arctic regions of the Earth. Safronov and Rouskol¹⁰ argue that water could not have escaped slowly from the lunar interior and formed oceans because the escape rate of water from the Moon would be so great that only a very small atmosphere of water could have accumulated. This conclusion is correct, and sources of surface water, which have been suggested, have been of a catastrophic kind, that is, a degassing of the lunar surface and the colliding objects in the great collisions on the Moon¹, a great splash from the Earth during the period of accumulation of the Earth2, comet head collisions, etc. I'1 suggested that the lake-like areas near and on the walls of Alphonsus were indeed caused by water (see under Moon, Encyclopaedia Britannica, plate III, for pictures of these). Gold suggested that the great central mass in Alpetragius is a pingo*. I3 have

argued that the carbonaceous chondrites may come from the Moon, for those of the type I variety, particularly. show that they were once immersed in water and that the Moon has certainly had liquid water on its surface.

Schroeter's valley, to the west of Aristarchus, has been known since the late eighteenth century, but terrestrial observations could not establish its origin. Orbiter 4 and 5 pictures show this valley in great detail as well as many neighbouring valleys. Schroeter's valley begins in a mountainous region in an enlarged area called the "Cobra Head", and extends in a generally westerly direction into a smooth maria area. Its greatest width is some 8 km and its depth some 600 or 700 m. Other smaller valleys with "cobra heads" are found north of Aristarchus and Prinz. Branching occurs in a few cases but mostly there are no tributaries and no deltas. Possibly there are small deposits at the maria ends, but they are much too small to account for the materials eroded from the valleys. South of Aristarchus and northerly from Marius is a valley extending to more than 160 km in a very smooth maria area. It decreases gradually and uniformly in width from the south-easterly end to the north-westerly end where it runs off the picture available to me (Orbiter 4, frame 150, high resolution). Near the larger end it is about 900 m wide and apparently goes to near zero at the other end. It is a very crooked rille and cannot possibly be a physical fracture. It has no tributaries. Similar rilles are found in many places, for example, within and near the Alpine valley and many other areas. They seem to be a general lunar feature.

But why are there no sediment deposits at either end of these valleys and no tributaries? (There are a very few examples of tributaries.) The walls seem to be formed by slumping, and north of Krieger there is a row of craters which seem to form an initial stage of such slumping. Water must have run below the surface and formed a tunnel which then caved in. But where did the excavated material go? If the maria are underlaid with ice, it is only necessary to melt the ice and let the water drain into the desert sands. (The explanation offered here was suggested by Gold.) But could it have been lava? Would lava flow in a narrow stream for hundreds of kilometres and disappear without a trace? I believe that the answer to both these questions is "No". But the details of these valleys are very varied.

While flying over northern Greenland on September 9, 1967, I saw crooked rille-like structures in the Greenland ice cap. Some of these looked like fractures but others, at least over limited regions, looked much like the crooked rilles on the Moon.

Krieger, north of Aristarchus, is an irregular crater with a recent smaller collision crater on the southern wall, a curious depression in the plane south of the crater, and an irregular mass covering the north wall and an area north of the crater. There is a break in the western wall, and from this break an irregular gully or stream bed extends a short distance to the west. This seems to have been a surface stream, and a suggestion of a sediment deposit can be seen at its western terminus. This appears to be a surface stream bed quite different from the other rilles discussed. North of Prinz one of the small rilles of the Schroeter valley type crosses an elongated sunken area, transverse to this valley. It has a flat floor, and a small stream bed, similar to that coming from Krieger, crosses it. These two stream beds indicate that streams flowed on the surface and thus that an atmosphere had a pressure equal to and probably much greater than the vapour pressure of water at its melting point, that is, 4.6 mm of mercury. Could Krieger be a pingo that has melted and collapsed? If so, it is a very large example as compared with terrestrial pingos. Krieger is 25 km in diameter. I have found a picture of a terrestrial pingo 300 m in diameter¹². But in a billion years, say, it may be that pingos get very much larger. Are there unmelted and uncollapsed pingo areas on the Moon? Probably

^{*}In regions of permafrost, that is, northern Canada and Siberla, great cones of ice covered with soil are formed by water and ice being extruded from the lower regions. They often look like small volcances with sloping sides and a depression like an irregular volcanic cone at the top. In some cases the ice has melted leaving a crater much like lunar craters but of much smaller diameter^{18,13}.

some of these volcanoes which are referred to so confidently are pingos.

South of Aristarchus is a crater similar in size to Krieger (name unknown; it appears on Orbiter 4, picture frame No. 150, 1 of 3 high resolution). There is a break in the northern wall and there is a rather smooth pile of sediment outside the crater at this point. Some liquid drained out of the crater and left this material. Possibly this was lava, or mud, or a flow of dust and gas. In view of the overwhelming evidence for water as the agent producing the other valleys, I favour the view that effects seen in this crater as well as Krieger are caused by water.

In fact, as mentioned here, several serious students of the Moon concluded, or at least surmised and suggested, that water was present on the Moon at some time in the past. This evidence for lake-like structures has been presented repeatedly, each author discovering for himself the same evidence previously recorded by others. The suggestions were reasonable and the evidence valid. The fact that there seem to be no mature river valleys anywhere argues that these seas were present for only a short length of time. It is not possible to give the time at which they were present. Was it 4.5×10^9 yr ago when the Moon was captured by the Earth, and may the Moon have captured some water from the Earth at that time, or was it some 2×10° yr ago when the Moon's orbit changed from retrograde to direct and when the Moon was near Or has the surface water appeared repeatedly? Thus water may have been acquired by the Moon early in its history; it escaped into space leaving water below the surface; the atmosphere was lost and low temperatures below the surface were established. Then a comet collided with the Moon, gave it an atmosphere, the temperature became warmer as on Earth, water melted and flowed out of the surface in springs. The atmosphere escaped and the water froze again until the next comet collision. The Safronov and Rouskol arguments seem to be valid and only a catastrophic origin for the water on the Moon seems possible.

Undoubtedly, someone will eventually measure and record these stream beds in great detail. This communication is to point out that the maria of the Moon are dried-up or frozen seas3-5 and that water has aided in forming the final features of the Moon. These conclusions in no way determine what the composition of the solid materials in the maria may be or whether this material had a

volcanic or other type of origin.

Core Convection, the Earth's Figure and Continental Drift

CERTAIN consequences of convection within the Earth seem to have been overlooked by those trying to establish satisfactory Earth model.

Variations of the geomagnetic field, and in particular the westward drift of its pattern of disturbances1, which have received considerable attention in relation to the Elsasser-Bullard hydromagnetic dynamo theory of the origin of the geomegnetic field, are widely regarded as signifying the existence of convection currents within the Earth's core. It has been argued that the heat required to drive these currents might arise from a quite small amount of radioactive material concentrated in the inner core. Another view³ is that the currents are produced by the energy released by gravitational differentiation into the inner core. Either mechanism would cause convection throughout the depth of the outer core.

The occurrence of free convection throughout the outer core would imply a uniform angular momentum per unit mass of outer core material and, because the ratio of the outer to inner core radius is 2.53, an inner core (assumed solid) rotating some $(2.53)^2 = 6.4$ times faster than the outer layer of the outer core. The moment of inertia of the Earth may be defined as that quantity which, when multiplied by the angular velocity, ω_c , of the crust, gives the Earth's total angular momentum. The slowness of the westward drift of magnetic field disturbances1 and the likelihood of tight electromagnetic coupling between the mantle and the outer layer of the outer core4,5 would then justify the view that the angular velocity of the inner core is about 6.4 wc, and that the angular velocity within the outer core decreases with increasing radius from this The angular momentum of the core as a value to ω_c . whole would thus be considerably greater than if it all rotated at ω_0 . Taking the values given by Birch⁶ as representative of recent models of the Earth's internal density distribution, an approximate calculation shows that the effective moment of inertia of the core would be doubled and the effective moment of inertia, C, of the whole Earth about its rotation axis increased by about 9 per cent. Note that the Earth's moment of inertia, A, about an equatorial axis would be unaffected (unless the core rotated about a different axis) so, in principle, observations of C-A could throw light on the amount of convection occurring in the core.

Jeffreys' has stressed that the hydrostatic theory of the Earth's figure, even when taken to the second order, yields a value for the precessional constant, H = (C-A)/C, which is significantly (about 1.1 per cent) less than that derived directly from lunar observations. The theoretical value of the quantity $J_2 = (C-A)/Ma^2$ is also about 1 per cent less than that derived directly from satellite observations^{7,8}, so the theoretical and observed values of C/Ma^2 are in substantial agreement. It follows that C-A is actually some I per cent greater than the hydrostatic theory provides, and the discrepancy is of the right sign for attributing to core convection. Because, however, H is of order 1/300, a 1 per cent change in C-A could be brought about by only a 1 in 3×10^4 change in either C or A. This is to be compared with the 9 per cent increase in C to be expected with free convection, and suggests that convective transport of angular momentum within the core is very small. It would be useful to know whether the magnetic field in the core could be responsible for this discrepancy and, if so, whether the field distribution implied by the Elsasser-Bullard theory of the geomagnetic field is of the right kind. Conversely, can that theory continue to account for the geomagnetic field if differential rotation within the core is as limited as these observations imply?

An interesting possibility in this connexion is that, if the persistent decrease of the chief geomagnetic field during the past 130 yr, amounting to more than 6.3 per

cent in all', has been associated with a general decrease in field strength within the core, there should have been a corresponding increase in the inward transport of angular momentum by the convection system. This would be expected to increase not only the westward slip of the outer layer of the core with respect to the mantle, but also the axial moment of inertia (possibly observable as an increase in J_2), and to reduce the angular velocity of the mantle and crust. The scatter of the westward slip data for magnetic disturbances is likely to be too great for a convincing correlation with the main field strength to emerge, if present, and the analysis 10 of observed variations of ωc during the past century is already beset by uncertainties as to the relative weight of the several possible causes. On the other hand, J_2 can now probably be determined from satellites with a precision of about I part in 104 (ref. 8). If we therefore regard 1 per cent of J_2 as being subject to control by the magnetic field in the core, a 1 per cent reduction in field strength might have a detectable effect on J_2 . It is unfortunate that the present rate of decrease of field strength is only about 3.5 per cent every century, because it could be another 30 yr before we know whether J_2 is affected in this manner. Any proof of lack of correlation between these parameters would imply that the chief external geomagnetic field strength is not correlated with the intensity in the inner part of the core and would place important restrictions on the nature of the geomagnetic mechanism.

This discussion shows that core convection is an extremely powerful cause of oblateness and can easily account for the observed excess over that given by the hydrostatic theory. Because it seems that core convection is essential to the generation of a geomagnetic field, and because the constraint imposed by the field is never likely to be very precisely calculable, the excess oblateness argument that the mantle has considerable long-term strength is now untenable. This does not mean, however, that the mantle does not have long-term strength, because the oblateness no longer provides evidence of continued retardation of the Earth's rotation, and Brouwer¹¹ has shown that the eclipse observations over the past few thousand years do not altogether confirm it either.

Convection within the mantle has long been favoured by proponents of continental drift, so, in view of the possibility that the mantle has very little long-term strength, the following argument may be of interest. If the outer layer of the core is the source of the observed geomagnetic disturbances drifting westward and is tightly coupled to the base of the lower mantle, it follows that the base of the mantle rotates at substantially the same rate as the crust. Thus free convection in the lower mantle, which would cause its base to rotate at something like 2.5 ωc, can be ruled out. Here again one wonders about the possible part played by the magnetic field, but the mean field will be much less than in the core, and the convective forces, with which the magnetic forces would have to compete, would need to be greater than in the fluid core, so adequate magnetic control can probably be ruled out, too. The possible argument that there is mantle convection but no core-mantle coupling can also be ruled out on the grounds that the observed nearsynchronous rotation of the crust and the outer part of the core (the angular velocities differ by only about 2 parts in 10°) would then have to be a mere coincidence. Similar arguments, much reinforced by those of Bernal^{12,13} and MacDonald14,15 in regard to upper mantle structure, and by recent evidence16 for phase transitions within the upper mantle, can be applied to convection in the upper mantle. It therefore seems that some other mechanism for continental drift will have to be found.

The proposed rotational condition within the core might have arisen as follows. Before the onset of core convection the Earth rotated rather faster. Onset of convection caused the rotation of the inner part of the core to speed up, but the corresponding slowing-down of the outer part of the core had to be shared with the mantle, because of the development of electromagnetic coupling between them.

Radiative Thermal Conductivity in Planetary Interiors

Ir is customary to invoke radiative thermal conductivity as a mechanism for efficiently removing heat from the Earth's interior1. Clark2 derived the formula

$$C_r = 4/3 \int_0^\infty \left(\frac{n^2}{\alpha + s}\right) \frac{\partial B(\lambda, T)}{\partial T} d\lambda \tag{1}$$

for radiative thermal conductivity in planetary conditions, where n is the refractive index, B is the blackbody function, λ is the radiation wavelength, α is the absorption coefficient and s is the backscattering coefficient. He used this relationship to estimate the radiative conductivity for a number of minerals by measuring α at room temperature and neglecting s (ref. 3).

We have shown4 that, in addition to their importance for terrestrial thermal calculations, the values taken for the thermal conductivity of rocks and minerals are critical in estimates of the likelihood of volcanic activity on the Moon. We have therefore investigated radiative transfer in minerals^{5,6}, including both an experimental study of the effect of high temperatures on the optical constants of minerals, and the detailed theory of backscattering.

The scattering calculations support Clark's neglect of s for particle sizes exceeding I mm. An interesting result of the theory, however, is that the diffuse backscattering is caused almost entirely by refraction rather than reflexion when the relative refractive index across particle boundaries is less than 4.

The experimental study involved measuring reflectance and transmittance spectra of minerals at temperatures up to 1,500° K and then calculating the optical constants. The minerals studied were diopside, peridot and oligoclase. Table 1 shows values of the radiative conductivity at high temperature, calculated from equation (1), using both high temperature and room temperature values of α and n. It is seen that the use of the high temperature data can reduce the calculated conductivity by a factor of as much as 20. This results from the band broadenings which cause increased absorption in the wings of the long wavelength silicate vibrational bands near 4µ and in the wing of the 1·1μ Fe2+ electronic band in the vicinity of 2μ. For any crystal containing Fe2+ these band broadenings close down the near infrared window and thereby result in Table 1. RADIATIVE CONDUCTIVITY (W/cm °K)

Mineral	
Peridot (at 1,513° K)	
Using room temperature spectral data	0.446
Using 1.513° K spectral data	0.0212
Diopside (at 1,513° K)	
Using room temperature spectral data	0.516
Using 1,513° K spectral data	0.102
Oligoclase (at 1,303° K)	
Using room temperature spectral data	0.425
Using 1.303° K spectral data	0.255

Values were calculated from near infrared optical properties as measured

a decrease in photon mean free path and thus radiative conductivity. The oligoclase, containing no Fe2+, shows a smaller decrease in radiative conductivity (a factor of about 1.7 at $1,300^{\circ}$ K) as the band broadening only occurs on the long wavelength side of the relevant wavelength region.

MacDonald¹ was the first to indicate that estimates of the 1,500° K radiative conductivity less than 0.03 W/cm °K appeared to be necessary in calculations of the thermal history of the Earth, although the values suggested by room temperature spectra of olivines were more than an order of magnitude larger. We believe that the results reported here go a long way towards resolving this

apparent difficulty.
We thank L. A. McClaine and B. Peatie for their assistance and Professor C. Frondel for the samples of diopside and oligoclase. This work was supported in

Ordovician Graptolites from the Kashmir Himalayas

THE discovery of graptolites near the village of Harpatnar in the Anantnag District of Kashmir¹ was of considerable interest to geologists studying the history of the Himalayas, because the apparent absence of graptolites from the Himalayas had long been the subject of considerable debate and speculation. The graptolites (described in ref. 2) indicate a Ludlow (Late Silurian) age for the Harpatnar Beds from which they were collected2.

A continuous and apparently conformably stratigraphic succession can be recognized stratigraphically above the highest graptolite-bearing layers in the Harpatnar Beds2, which are overlain by the Naubug Beds from which fish3 and conodont faunas4, indicative of an early Middle Devonian age, have been obtained. The stratigraphic succession beneath the lowest graptolite-bearing layer in the Harpatnar Beds is, in contrast with the layers above, faulted. Despite the structural complexities, a unit of red mudstones and shales can be recognized in a slice beneath the Harpatnar Beds which is bounded by faults. A collection of graptolites has recently been made by one of us (V. J. G.) from this slice.

The newly found graptolites are poorly preserved fragments. The following forms can, however, be recognized among them: Climacograptus sp.; Didymograptus sp. (juvenile stage of an extensiform didymograptid similar to D. compressus Harris and Thomas); Glossograptus ? sp. (a glossograptid, might be a paraglossograptid).

The association of this extensiform didymograptid with a climacograptid and glossograptid indicates an age span of late Early (approximately Late Arenig) into Middle (Mid-Caradoe) Ordovician. The association of extensiform didymograptids with climacograptids and glossograptids is known in the British and Continental European Ordovician graptolite successions from the British Didymograptus hirundo Zone and strata correlative with it into the Climacograptus bicornis Zone. This association of graptolites is known in the American-Australian-Asian Ordovician graptolite successions to range from beds. considered correlative with the basal part of the British Llanvirn, into those correlative with the British Climacograptus bicornis Zone.

The presence of the extensiform didymograptid, similar to D. compressus, suggests that the fauna may have had connexions with the American-Australian Asian Ordovician graptolite faunas rather than the British-Continental faunas. This didymograptid species is restricted to the American-Australian-Asian Ordovician graptolite fauna where it occurs in faunas considered to be correlated with those of the British Llanvirn.

These are the first conclusively Ordovician graptolites to have been found in this part of the Himalayas. Their presence in this area indicates that deposition of finegrained terrigenous materials took place, at least locally in the Himalayas, during at least a part of the Ordovician. These graptolites are the oldest fossils from the area southeast from Srinagar. Their presence thus indicates that marine deposition did take place in this part of the Himalayas and that, during at least a part of both the Ordovician and Silurian, graptolites were able to live in the waters in this area. The possibilities of the faunal connexion with the American-Australian -Asian graptolite faunas are significant to the palaeozoological distribution of Ordovician faunas. The Himalayan area may have been allied faunally with Asia during at least a part of the Ordovician.

PHYSICS

Bursting Air Bubbles studied by the Time Exposure Technique

THERE are several mechanisms by which particulate matter is transferred across the sea-air interface. Filaments of liquid are torn from the tops of whitecaps by the wind and are generated by the break-up of combers. The mechanism of greatest meteorological importance is, however, the bursting, at the interface, of bubbles of air which have been trapped under the water surface or have been released from solution.

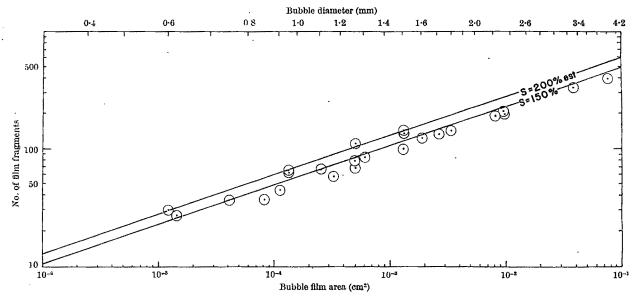

Fig. 1. Number of film fragments, counted from photographs taken in the cloud chamber, plotted as a function of bubble film area (or bubble diameter). Lines represent loci of counts made at constant maximum supersaturations, S. Supersaturation vertical profiles in the cloud chamber are extremely non-linear. At some maximum supersaturation, near 250 per cent, all bubble film fragments formed are caused to grow large enough so their scattered light exposes the photographic film.

Earlier studies¹ of bursting bubbles clearly identify two explosive actions which are intimately related, but are quite distinct. (1) The liquid surface of the ruptured bubble snaps back to re-establish a configuration of minimum surface energy. In the process a liquid jet shoots rapidly upward from the bottom of the bubble cavity, develops instabilities² and necks off into several drops and droplets (provided that bubble diameters do not exceed 5–6 mm). (2) Small fragments of liquid, torn

Imm

Fig. 2. Time exposure of a 2-2 nun diameter bubble bursting in artificial sea water. Jet drop tracks are indicated by a broad white line. Pulsing of the mercury are lamp leaves a useful 1/120 sec time marker. Four jet drops are visible in this picture. Note the irregular bouncing of jet drops as they hit the water surface. Bubble film droplets grow to visible size by the time they reach the top of their parabolic trajectories. Then they sink slowly back to the water surface. The duration of the entire burst event is less than 2 sec.

loose from the retreating bubble film, are projected upward by the explosive release of the excess gas pressure in the bubble. These bubble film droplets are then further entrained in the wake of the ascending jet.

The principal mechanism which initiates the rupture of the bubble film is not well understood. After reaching a critical thinness by drainage and evaporation, the film may well require a triggering mechanism such as the nucleation of the gases absorbed in the liquid before it actually ruptures³.

The mean number of bubble film droplets has been found to be dependent on the size of the bubble. In an earlier investigation⁴, bubbles with a diameter of 4 mm equiv., breaking in saline solutions, were found to produce from 300 to 400 bubble film droplets while 0·1 mm bubbles produced no bubble film droplets. Fig. 1 shows that, with an improved model of the thermal diffusion cloud chamber, capable of running at higher supersaturations, somewhat larger numbers of droplets can, as expected, be counted.

I have taken time exposures of individual bubble bursts in their entirety as another means of understanding the motion of the jet drops and the bubble film drops. The type of information which a time exposure of a single bubble burst yields is illustrated in Fig. 2. One positive clarification emerges from an analysis of many of these pictures; it is that, contrary to earlier conclusions of Blanchard, myself and others, the bubble film droplets do not participate in a vortex ring circulation. The bubble film droplets seem to rise, and then fall back to the water surface along regular parabolic trajectories.

The bubble film droplets evaporate very rapidly in the free air because of their micron and submicron size range. Because of this, a film droplet of salt water is more likely to become an aerosol particle than is a jet drop, which, by virtue of its larger size, does not evaporate so rapidly. This probability factor, however, must be counterbalanced by the fact that the sea contains bubbles ranging in size from microscopic to diameters measured in millimetres, and the smaller bubbles far outnumber the larger ones. Bubbles smaller than a few tenths of a millimetre in diameter seem to produce no film droplets. Yet as the bubble diameters get smaller, so do their jet drops. This increases the probability of jet drops from small bubbles contributing substantially, along with the bubble film droplets, to the salt aerosol population of the atmosphere.

Hysteresis Loop Experiments and the Determination of Thixotropic Properties

HARRIS¹ has pointed out the added complication in interpreting the "hysteresis" loop experiment for determining thixotropic properties which arises from the combined effect of the moment of inertia of the inner cylinder of the coaxial cylinders viscometer coupled with the stiffness of the torsion spring used in torque measurements. Huxley² has shown how this effect can be eliminated for Newtonian fluids. Steady-state oscillatory¹ and transient² experiments have been suggested for determining thixotropic properties. With this renewed interest on thixotropic behaviour, I shall summarize the results of my investigations into this phenomenon, outline work in progress and indicate the future lines of research.

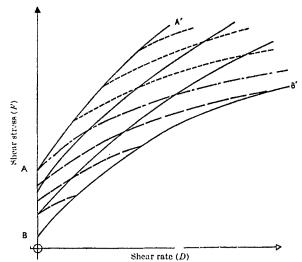

The basis of my work is a phenomenological theory of inelastic thixotropic behaviour based on the concept of thixotropic structure3. There is another theory based on the concept of relaxation spectrum due to Harris's. My theory is a generalization of three 5-7 specific model thixotropic or antithixotropic fluids in which the thixotropic behaviour is given in terms of the constitutive equations consisting of (a) an equation of state $F = \eta(D, \lambda)D$ which relates the shear stress, F, to shear rate, D, for any given state, λ , of the thixotropic structure, and (b) a rate equation which can be given in terms of the shear rate $d\lambda/dt = g(D,\lambda)$ and relates the rate of breakdown or build-up of the thixotropic structure. With certain specific restrictions on the forms of the functions n and g, these constitutive equations describe all the rheological behaviour associated with thixotropic and antithixotropic fluids.

The constitutive equations are shown in Fig. 1. can be mapped by a grid of constant structure, λ (solid lines), and constant rate, g (broken lines). The map is bounded by two constant-structure lines representing the state of maximum possible structural build-up, AA', and the state of maximum possible structural breakdown, BB'. Constant structure lines for intermediate states are between these limits. The constant-rate lines cut the constant-structure lines at an angle. The situation for a thixotropic fluid is shown in Fig. 1. The chain dotted line, running from A to B', represents zero rate and is referred to as the equilibrium curve. The dotted lines are lines of negative rate representing structural breakdown, and the dashed lines are of positive rate representing structure build-up. Thus the "maximum" representing structure build-up. Thus the structure is attained only at rest, and the "minimum" structure at very high shear rate. For an antithixotropic fluid the acceptance is fluid the equilibrium line runs from B to A' and the other constant-rate lines are similarly placed; the "minimum" structure is now attained at rest, the "maximum" structure at very high shear rate. It should be noted, however, that no real fluid has yet been clearly shown to be antithixotropic according to this description.

Experiments should ideally lead to, or be capable of being converted into, the constitutive equations. work of Billington and Huxley goes partly towards this. Billington^{8,9} first used the coaxial cylinders viscometer to observe the transient response of the inner cylinder in conditions of constant rotational speed of the outer cylinders and constant applied torques, and deduced the shear stress and shear rate variations, respectively, as the structure altered with time for "wax-containing" oils. In later papers, Billington and Huxley^{10,11} showed that. for oils containing either aluminium laurate or colloidal graphite, thixotropic breakdown did not begin until the shear stress had increased beyond a certain value. This allowed them to derive the shear stress-shear rate relation for the fluids at the state of maximum structure. They also obtained the equilibrium curves. Earlier^{8,9}, however. two factors seemed to have been neglected: the variation of shear rate in the annular gap between the cylinder and the non-uniform rate of thixotropic breakdown arising from the non-uniform shear rate and the resultant nonuniform structural states in the sample fluid. Thus, although Billington⁹ found it possible to compound the shear rate-time curves for different shear stress into one. it is doubtful whether the corresponding points on the individual curves do represent the same structural state. Later^{10,11}, the variation of shear rate was effectively allowed for, but no time variation curves were derived pertaining to thixotropic breakdown. Investigators^{2,10,11} contented themselves with stating that this is in principle possible.

Knowing that non-uniform conditions could exist within the fluid sample, my experimental work was directed towards determining constant-structure lines and deriving constant-rate lines. The use of the coaxial cylinders was first examined3. An experimental procedure was devised which involved shearing the sample at some reference speed to a steady state, suddenly changing the speed to a new value, and observing the resultant change of torque with time. Determining the constantstructure lines from the experimental data is relatively straightforward, and an example of such results, using a 'Rheomat 15' viscometer (Contraves AG, Zurich), is shown in ref. 3. It is, in principle, also possible to determine the rate equation from the experimental data, but in practice it means that some function has to be first assumed and it is the values of the parameters involved that are determined. In any case, the treatment necessary is not

The cone and plate viscometer has the reputation of giving uniform shear rate. The validity of this characteristic was therefore examined, and it was shown¹² that

during steady rotational motion, provided that the cone angle is less than about 4°, the approximation is very good. The error involved was no greater than errors inherent in any apparatus and was certainly much less than the variation possible between samples of the usual fluids that exhibit thixotropic properties. The same experimental procedure, as described here, can again be used and it is shown that the treatment of experimental data to derive the constitutive equations is very straightforward¹². It therefore seems that the cone and plate viscometer would be ideal for determining thixotropic properties. None of the commercial cone and plate instruments we possessed at the time was capable of the step-change in speed required for the experimental work. A special gearbox was therefore designed and built for use with a rheogoniometer (Sangamo Controls, Ltd., Bognor Regis), and work is now in progress to determine the constitutive equations for certain thixotropic aqueous clay suspensions.

It is appreciated that this method for determining thixotropic properties is time consuming and would not be practicable for industrial purposes, and some other rapid method for assessing thixotropic properties is therefore necessary. To this end the "hysteresis" loop test devised by Green and Weltmann (see references in ref. 1) or the oscillating experiment suggested by Harris¹ could be used. When coaxial cylinders are used for these tests, however, in addition to the objections pointed out by Harris1, there is the existence of shear rate and structural variations in the sample to take into account and this would make the detailed interpretation of experimental data even more complicated. The tests could still be used, particularly in industry, as a rapid means of ranking different thixotropic fluids or for the purpose of quality control for which detailed reduction of data is not necessary.

A commercial instrument, the Ferranti-Shirley cone and plate viscometer, is available which performs the loop test and is widely used in the clay, paints, printing ink and other industries. Its performance is also influenced by the combined effect of cone inertia and the torsional stiffness of the torque spring. This effect has been discussed earlier¹³. In the course of experiments, to test the validity of certain formulae which we have derived for the correction of these effects, it became apparent that other factors also influence the performance of the instrument. Because the loop test can also be used as a semi-automatic means of determining the flow curves of time-independent purely viscous non-Newtonian fluids, and has the added advantage that viscous heating can be minimized if it is carried out rapidly, the effect of these influences is being studied in detail.

The experiments using various Newtonian fluids covering a three-decade range of viscosity have been completed. Both positive and negative loops were obtained, depending on whether the viscosity is less or greater than certain critical values depending on the inertia of the cone involved. The retarding torque on the cone at any instance of the test, because of the fluid under test, can be deduced from these loops, after allowing for the effect of cone inertia and torsion spring stiffness. It was found, however, that the value of the torque differs from that expected from the theory for steady rotation12 using the speed of the cone at the same instant of time. It therefore seems that some other factor or factors are also involved. Two factors are being considered, both having their origin in the inertia of the fluid, but it is convenient to separate them into "secondary flow" and "inertia"

It is known that because of the geometry of the cone and plate, the primary flow usually assumed for such viscometers¹² cannot be absolutely valid when fluid inertia is not negligible, and more complex, or secondary, flow must always occur¹⁴. The effect of secondary flow, with steady rotation of the cone and plate, has been studied both theoretically and experimentally for Newtonian fluids and it was shown that the effects cannot be ignored. During the loop test, the rotation is far from steady, and it is thought that the effect of secondary flow could be even more pronounced.

During the loop test, the fluid is subjected alternately to acceleration and deceleration, and the corresponding inertia terms in the equation of motion cannot be ignored. (It can be readily shown that, in the coaxial cylinders geometry, inertia terms can be safely neglected.) If the effect of secondary flow is neglected, the equation of motion remains linear and, after using Fourier analysis on the rotational speed of the cone, the problem reduces to that of steady state oscillating motion, solutions of which are, of course, available 16,17. We are now in the process of applying these results and it is hoped to be able to judge the relative importance of the "secondary

flow" and "inertia" effects in the loop test.

From a practical viewpoint the results for Newtonian fluids using different cones can be correlated by a suitable reduction of the experimental data and the correlation can be used to correct the loop results for the various effects noted. Work is now in progress to test whether the same correlation can be applied to non-Newtonian fluids. In the future, it is planned to apply the same method of data reduction to loop tests with thixotropic fluids. The corrected loops will have to be compared with those calculable from the constitutive equations determined using the special gearbox and the rheogonio-

Orifice Plate Calibration in a Dilute Polymer Solution

THERE have been several experiments in which the turbulent skin friction in pipe flow is reduced by adding certain soluble macromolecular polymers to a flowing solvent. The polymers do not seem to affect the turbulence in the core of the flow¹, but rather cause a thickening of the viscous sublayer². Drag reduction, it seems, requires the presence of a wall.

Gadd^{3,4} and Jackley⁵ have reported tests on free jets. In the case of initially turbulent free jets4.5, no difference was noted between the behaviour of jets of water and jets of polymer solutions. In the case of initially laminar free jets^{3,4}, however, dye tests revealed a considerable difference in the behaviour of water and polymer solutions. In polymer solutions there seemed to be a marked suppression of small-scale turbulence. Because polymer solutions apparently do not affect the turbulence away from the wall in pipe flow, the results of tests on initially turbulent free jets are to be expected. The results for laminar free jets, however, at first seem surprising. From

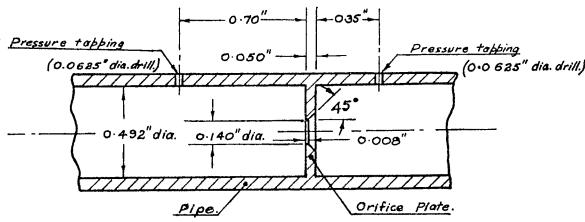

Fig. 1. Details and dimensions of the orifice plate.

the appearance of a photograph included in ref. 3, I am tempted to think that the polymer inhibits the transfer of turbulence energy from the low wave-number at which the large initial eddies were formed—because of the instability of the toroidal vortex sheet created by the jet-to higher wave numbers. This effect may be unrelated to the phenomenon of reduction of turbulent drag in pipe flow, especially because not all polymers of comparable drag reducing properties affect free laminar jets (for example, guar gum does not)4.

After carrying out some pipe flow experiments, I have noted a considerable reduction in pressure drop across an orifice plate. Workers would be well advised not to assume the calibration of an orifice plate for a dilute polymer solution to be identical with that for water. An orifice plate, of the dimensions shown in Fig. 1, was calibrated in turn for water and for a 30 w.p.p.m. (weight parts per million) aqueous solution of 'Polyox WSR-301' (polyethylene oxide) donated by Union Carbide (Australia), Ltd. The results are shown in Table I and Fig. 2. For flow rates above the order of 1.5 lb./min the pressure drop across the orifice was approximately 11 per cent less for the 'Polyox' solution than for the water. At lower rates no significant difference was noted. The results were first plotted on a log-log scale. The data for both the water and for the 'Polyox' above flow rates of 1.5 lb./min seemed to lie on curves of slope +2. Because of this, a least squares parabola was fitted to each of these sets of

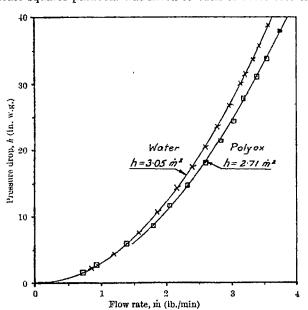

Fig. 2. Curve of pressure drop against flow rate for water (×) and 'Polyox' (□). Temperature is 61° F. Age of solution, 30 h.

Wa	ter	Table 1	'Poly	nx'

2.4	0.865			

points. The resulting curves are shown in Fig. 2. These results are difficult to reconcile with other experiments mentioned earlier. If it is considered that there is a region of high shear rate in the orifice similar to a viscous sublayer in pipe flow, and that this region is thickened by the addition of polymer molecules, it is questionable whether the decrease in pressure drop would be similar to that shown in Fig. 2. It should be noted that, in the case of the pipe flow, the amount of drag reduction increases with Reynolds number, while in the case of the orifice the amount of reduction in pressure drop remains constant within the order of experimental accuracy. In view of this it seems that the cause of the effect is different from that in pipe flow. Considering an orifice to be somewhat akin to a free jet, then, according to results of experiments on jets4,5, the decrease in pressure drop would be expected to become less pronounced as the flow became turbulent, that is, with increasing flow rate. Clearly, this is not the case. The mechanism seems to be different from both that present in free jets and that present in pipe flows.

Measurement of a Mass Transfer **Boundary Layer**

DATA on momentum transfer from velocity measurements are usually applied to mass transfer processes using the accepted analogies between heat, mass and momentum Doubts about these analogies, in particular transfer1.

their application to turbulent flow, have led me to develop a method of measuring the wet bulb depression of water vapour in a mass transfer boundary layer formed by water evaporating into moving air above a flat porous plate. The efficacy of the method, in a laminar boundary layer, has been established by comparison with the Blasius boundary layer equation for mass transfer¹.

Because of the difficulty of measuring mass concentration in a small space, little attention has been given to the mass transfer boundary layer. Powell and Griffiths² used a wet-bulb thermocouple to investigate evaporation from variously shaped bodies, but they were more concerned with overall evaporation rates than detail of the boundary layer. ElWakil et al.³ used an interferometric technique.

I have developed a method, with the fine spatial discrimination required, based on the same principle as that first proposed by Hill4 for measuring vapour pressures above aqueous solutions, and developed by Spanner⁶ for measuring vapour pressures associated with leaves. The Spanner method has since been used widely for botanical studies6,7 and soil studies8 although in still air only. The Spanner method uses the thermo-electric effect to cool the junction of a thermocouple below the dewpoint of the surrounding air so that condensation occurs and the thermocouple becomes wet. Spanner used a double throw, double pole switch to connect the thermocouple alternately to a battery circuit for cooling the junction and then to a galvanometer circuit which measured the junction temperature. Because of the slow response time of the galvanometer, the ballistic throw was recorded. A suitable d.c. amplifier and an oscilloscope enable the quite rapid temperature changes of thermocouple to be observed directly and continuously.

The feasibility of a wet thermocouple for measuring humidity in moving air was suggested by the work of Wylie⁹ and Powell¹⁰, who showed that as the diameter of an ordinary wet bulb thermometer is decreased, the threshold, above which the effect of air velocity is negligible, is reduced and the wet bulb depression approaches the temperature of adiabatic saturation, or the ideal wet bulb temperature. Similarly, as the thickness of the muslin covering the wet bulb is reduced, the wet bulb depression approaches the ideal. Thus it is reasonable to assume that data from a standard hygrometer can be applied to the thermocouple psychrometer.

There are certain difficulties in using such a psychrometer in the moving air of a boundary layer. The degree of cooling obtainable with metals is limited to about 8° F, thus the probe must be returned to areas of high humidity to rewet the junction. Rather than be continually rewetting the junction and then rapidly winding the probe through the boundary layer to the desired position, the

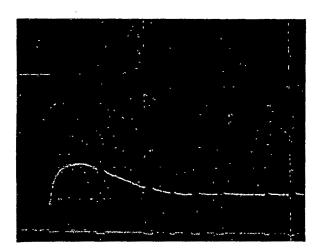

Fig. 1. The variation of wet built temperature through the boundary layer. The vertical displacement represents temperature and the horizontal scale is the height of the probe above the plate surface.

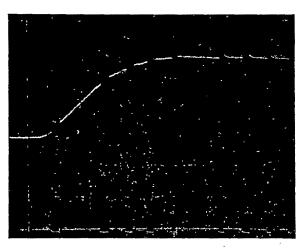

Fig. 2. The variation of temperature through the boundary layer with a thermocouple that has not previously been wet. The conditions are the same as for Fig. 1.

probe was motor driven through the boundary layer, taking measurements before all the water evaporated from the junction. The time available for the traverse was about 10 sec. It was found that the response time of the thermocouple and amplifying system was fast enough to give a true picture of the temperature change across the boundary layer.

The thermocouple used was of bismuth and an alloy of bismuth with 5 per cent tin. The wire diameters were 0-0015 in. and 0-0048 in., respectively. The thermocouple or Seebeck coefficient of the junction was 108 $\mu V/^{\circ}C$. A d.c. amplifier was used to amplify the signal from the thermocouple, which was fed to an oscilloscope and photographed.

A laminar mass transfer boundary layer was produced by evaporating water through absorbent paper placed on 50 per cent porosity sintered bronze plates measuring 24 in. \times 6 in. The plates were mounted in a horizontal position on the floor of a wind tunnel. The wind velocity was such that the air flow was laminar at the measuring station.

Fig. 1 shows the variation of wet bulb temperature through the boundary layer. The vertical displacement represents temperature (in this case 1.66° F/cm scale division). The horizontal scale is the height of the probe above the plate surface (0.064 in./em scale division indicated by the lower trace from a displacement transducer). The free stream air velocity was 3.4 ft./sec, free stream humidity 66 per cent relative humidity and ambient temperature 60° F. The initial increase in temperature is caused by the temperature of the thermocouple junction increasing from the dewpoint to the wet bulb temperature as the thermocouple is switched from the cooling to the measuring circuit. Fig. 2 is of a traverse with the same thermocouple under the same conditions but without having previously been wet. This corresponds to a dry bulb temperature traverse, but the temperature indicated is relative to the thermocouple wire supports. Thus because of a small temperature gradient between the plate and the ambient air, there is a variation in the drybulb temperature through the layer.

The difference between the traces in Figs. 1 and 2 gives the wet bulb depression and thus the mass concentration across the layer. This has been plotted in the non-dimensional form in Fig. 3. The abscissa is familiar from boundary layer theory and is given by

$$\eta = y \sqrt{\frac{U_{\infty}}{vx}}$$

where y is the height above the plate (ft.), U_{∞} is the free stream velocity (ft./h), v is the kinematic viscosity of the air (ft.²/h), and x is the distance along the plate (ft.).

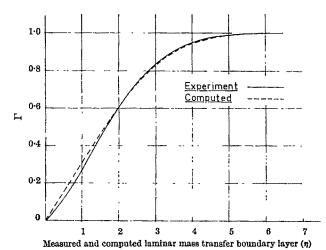

Fig. 3. The mass concentration across the layer in non-dimensional form. The continuous line is the experimental result, and the broken line is computed from Blasius boundary layer equations for mass transfer.

The ordinate Γ is a non-dimensional measure of the mass concentration and is given by

$$\Gamma = \frac{C_W - C}{C_W - C_\infty}$$

where C_W , C, C_∞ are the mass concentrations at the surface of the plate, at the position and in the free stream air, respectively (lb./ft.3).

To test the accuracy of the experimental data, a similar profile was computed from the Blasius boundary layer equations for mass transfer1. As can be seen from Fig. 3, the experimental data were in close agreement with the computed profile.

THE SOLID STATE

Growth of Single Crystals of Silver Halides in Silica Gels at Near Ambient Temperatures

THE growth of single crystals by controlled diffusion in gels at near ambient temperatures offers intriguing advantages for substances which are sparingly soluble in the gel medium or which dissociate at the high temperatures so frequently employed for crystal growth1, or both. The gel diffusion growth method has been described as most applicable to materials with solubilities in aqueous solutions in the order of 10-1 to 10-2 weight per cent at ambient temperatures2. We report the successful application of the gel growth method to substances, the solubilities of which range from 10-5 to 10-7 weight per cent, thus enhancing its use for preparing single crystals of quite low solubility substances.

O'Connor et al. have prepared single crystals of cuprous chloride in silica gels by the controlled decomposition of a soluble cuprous chloride-hydrochloric acid complexo. The concept of precipitating single crystals can be effectively used in preparing silver halide single crystals. Such crystals have been grown from the melt by the Kyropoulos method, the Bridgeman method, etc.4. as well as from solutions, the latter methods being limited to the growth of microcrystals which are of interest in the photographic industry. High dislocation densities introduced during cooling from the melt, and contamination with silver oxide, etc., are typical problems associated with crystal growth from the melt. Growth in gels at ambient temperatures may conveniently produce larger more perfect single crystals, employing very simple equipment and preparatory techniques.

Single silver bromide and iodide crystals were grown in

silica gels at near ambient temperatures by controlled decomposition of their soluble corresponding acid complexes, for example, $H^+[Ag(Br)_2]^-$ and $H^+[Ag(I)_2]$. Silver chloride single crystals were grown by controlled decomposition of the soluble ammonia complex $[Ag(NH_3)_2]$ CI- in preference to the corresponding acid complex H+[Ag(Cl)₂]-. When silver chloride crystals were grown from the corresponding acid complex, embrittlement invariably occurred during growth. This may be associated with the adsorption of complex ions of high negative charge [Ag(Cl)₄]⁻² in the vicinity of strained surface bonds⁶. The largest silver iodide crystals grown to date were hexagonally shaped platelets approximately 10 to 12 mm in diameter. The silver bromide crystals were cubic, approximately 1 mm per edge. The silver chloride crystals were octahedral or truncated tetrahedral 6 to 8 mm per edge.

Although standard grade, not specially purified, reagents were employed in these crystal growth studies, spectrographic analyses indicated that their total cation impurity content was in the order of 10-20 p.p.m., with silicon very low. X-ray diffraction studies of silver halide crystals grown in gels indicated a high degree of crystal perfection, as will be discussed here.

Typically, crystals of silver iodide were grown by the following procedure. Silica gels were prepared by mixing equal volumes of sodium silicate (Fisher certified reagent) solution of specific gravity 1-06 and acetic acid (5 normal). Such solutions (pH 4·1) were poured into 25 mm diameter test tubes and permitted to gel in the dark at around 25° C-a process which took 10-15 h. The resulting gel was covered with additional higher acidity gel (pH < 1.0). prepared by mixing equal volumes of the sodium-silicate solution and 3.91 normal hydriodic acid (CP grade). The volume of the top gel layer was approximately one-fourth of the bottom one. About 10 ml. of solution prepared by dissolving 10 g silver-iodide (CP grade) in 50 ml. hydriodicacid (3.91 normal) was placed over the above gel and Silver-iodide crystals became allowed to decompose. visible after about an hour. Spectrographic analyses of typical crystals gave the following results: copper. 5 p.p.m.; iron, 5 p.p.m.; aluminium, 5 p.p.m.; silicon. <5 p.p.m.; magnesium, <5 p.p.m.; calcium, <1 p.p.m. Elements checked for but not found included sodium. potassium, barium, zinc and lead.

The silver iodide crystals were also examined in a two crystal spectrometer. The 2d spacing of the large hexagonal shaped faces was measured and calculated to be 7.50 Å which, within the corresponding experimental error of the measurement, corresponds to the (0001) plane of hexagonal silver-iodide with a 2d spacing of 7.494 Å. A rocking curve half width of the diffraction profile, obtained with an ethylenediamine ditartrate reference crystal, indicated crystal perfection comparable with that of the usual crystals used as X-ray analysers.

Silver bromide crystals were grown similarly except that the top gel layer was prepared by mixing equal volumes of 4 normal hydrobromic acid (CP grade) and sodiumsilicate. The soluble silver bromide complex solution was made by dissolving 10 g silver bromide (CP grade) in 50 ml. hydrobromic acid (6 normal). Crystals of silver bromide belonging to the cubic system became visible after about an hour. Their maximum size was in the order of 0.8 to 1.0 mm and was attained within 8 to 10

As noted, for the growth of silver chloride crystals, best results were obtained by decomposing silver chloride ammonia complexes. Gels were prepared by mixing equal volumes of sodium-silicate solution (specific gravity 1.06) and 2.9 normal hydrochloric acid. After gelation they were covered with a top solution prepared by dissolving 10 g silver chloride in 50 ml. ammonium hydroxide (8.33 normal). After 10 to 12 days crystals of up to 5-8 mm in edge were obtained. Most of the crystals were octahedral or truncated tetrahedral forms.

Structural Changes of Barium Methacrylate Dihydrate under X-radiation

Schneller and Flanagan¹ have discussed the solid state decomposition of silver nitrite after irradiation with gamma rays. They noted that similar results were obtained by Boldyrev and Eroshkin³, who irradiated the compound with X-rays. We report similar work on the solid state polymerization of barium methacrylate dihydrate.

We have examined the structural decomposition of a sample of barium methacrylate dihydrate continuously irradiated with X-radiation. The experiment was performed on a finely powdered sample of barium methacrylate dihydrate left open to the atmosphere and mounted in a standard aluminium flat sample holder in a Philips PW 1051 wide angle powder diffractometer. A standard size collimator with anti-scatter slits of 1° diversion and an 0.1 mm receiving slit was used. Throughout the experiment the temperature remained constant at 25° C.

The kinetics were followed by measuring the decrease in the intensity of three powder diffraction peaks (100, 200, 002). The peaks were scanned at a speed of 0.125°/min at regular intervals of time and between scans the machine was left oscillating through the 20 range covering all three Intensities were estimated by weighing cut-out tracings of the diffracted peaks. The investigation was carried out at three different dose rates achieved by using: (a) nickel filtered copper radiation ($\lambda = 1.5418 \text{ Å}$) at 40 kV and 6 m.amp; (b) nickel filtered copper radiation at 40 kV and 20 m.amp; and (c) unfiltered copper radiation at 40 kV and 20 m.amp with a nickel filter placed between the sample and counter. The estimated dose rate (private

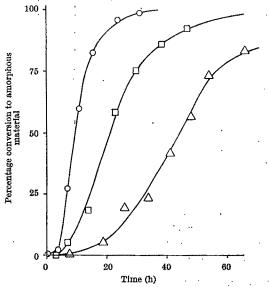

Fig. 1. Dose rate dependence of conversion of crystalline barium methacrylate dihydrate to amorphous material during continuous X-irradiation at 25° C. Mean lines for 200 and 002 reflexions. Dose rates: Ο, 556,000 rad/h; □, 205,000 rad/h; △, 69,500 rad/h.

communication from the Australian AEC Dosimetry Service) for each of these conditions is 69,500 rad/h, 205,000 rad/h and 556,000 rad/h, respectively. results are shown in Fig. 1.

O'Donnell, McGarvey and Morawetz³ have postulated, from electron spin resonance measurements, a free radical mechanism for the polymerization of barium methacrylate dihydrate induced by gamma radiation. Subsequent gravimetric determinations (results by J. H. O'Donnell and M. J. Bowden, to be published) of the kinetics of this polymerization show an expected increase in rate with an increase in the intensity of the irradiating beam. Our results show a marked similarity to those obtained by the gravimetric separation of polymer formed during the irradiation barium methacrylate dihydrate with gamma rays. As the large absorption coefficient of the compound results in a half-thickness of 20µ for the X-ray beam, the observed effect is a surface one and the comparison is only qualitative.

In view of the results of Schneller and Flanagan¹ and Boldyrev and Eroshkin², we feel that the comparison of our results with those found in the gamma ray polymerization of barium methacrylate dihydrate is justified, and that the observed structural decomposition is caused by polymer being formed. Further developments in the method we have outlined could provide a means of studying the kinetics of solid state polymerization in situ, thus overcoming a number of errors inherent in the normal gravimetric analysis techniques.

We wish to thank the Australian Institute of Nuclear Science and Engineering for supporting this work, Dr W. Layton and Mr S. Bagley for providing time on the Department of Geology's diffractometer and Mr R. D. Sothman for collecting some of the data. One of us (N. W. I.) received the support of an Australian Paper Manufacturers scholarship.

MOLECULAR STRUCTURE

Mössbauer Spectroscopy of Some Iron Porphyrins

The Mössbauer parameters of various iron porphyrin complexes have been investigated as model systems for haem proteins1,2. Topics which require further consideration are the effect of porphyrin structure, basicity and esterification on the Mössbauer spectra. It has been shown that the basicity 'towards protons of meso and diacetyl deuterohaemins differs by a factor of one hundred whereas their isomer shifts (δ_0) and quadrupole splittings (ΔE) were insensitive to this change². We have studied the water soluble N-methyl substituted meso tetrapyridyl porphine (unpublished results of Fleischer and Hambright), which seems to be the most acidic porphyrin known. The (pK_3+pK_4) of this compound is the same as the unmethylated derivative³, whereas $pK_2 = 12 \cdot 9$. No other porphyrin has a measurable pK_2 in aqueous solution. Table 1 shows that the isomer shift of this structurally different haemin compound and protohaemin chloride are almost identical This indicates in both a 5 per cent 4s electron contribution to the d^5 configuration of Fe(III), and that regardless of structure or basicity, the metalligand bonding in these high spin square pyramid chelates is primarily ionic. It is also noted that low spin octahedral hemichromes have approximately the same sigma electron density at the iron nucleus ($\delta_0 \cong 0.041$ cm/sec) as the high spin haemin chlorides, whereas ΔE of the low spin derivatives is, as expected, larger ($\Delta E \cong 0.21$ cm/sec) than that of the high spin compounds. This unexplained similarity is novel in that typical inorganic low spin complexes have more sigma density than high spin varieties, presumably because of their increased pi bonding capacities. Thus the similarity in δ_0 values might indicate a limited role for pi bonding in low spin ferric porphyrin systems.

has described the factors giving rise to the peak asymmetry indicated in Table 1.

BIOPHYSICS

Birefringence in Unfixed Lemon Fruit Nucleoli

CHEMICAL fixation of cells and tissues for microscopical analysis carries with it the stigma of artefact production1-5. Sjöstrand and Bakers have pointed out that the best way of checking for fixation artefacts is to employ a method of fixation or preservation of cellular components which acts on a completely different principle from chemical fixation. Cytological preparations of frozen and thawed lemon fruit tissue cultured in vitro are described here which show that the optically anisotropic nucleolar material first observed

- * Chemical shift reported relative to sodium nitroprusside.
- † Standard error on the basis of computed instrumental error +0.0004 cm/sec.
- ‡ All compounds gave satisfactory analytical data.

The data for protohaemin chloride were from a four times recrystallized analysed sample. It was found that commercial protohaemin from several sources contained ferromagnetic impurities (unpublished results of A. Thorpe). The susceptibility of this sample followed the Curie law to 70° K, giving a moment of 5.93 B.M. Room temperature data for the other compounds indicated high spin ferric derivatives.

Esterification of the propionic acid groups of the porphyrin has been shown to hinder the enzyme incorporation of Fe(II). It has been observed previously that with chloride or bis-imidazole groups, there is no Mössbauer difference between the acids or methyl esters. When acetate is the ligand (Table 1), δ_0 and ΔE are smaller for the dimethyl ester than the corresponding acid. These differences could be interpreted as inter- or intra-molecular hydrogen bonding between the coordinated acetate and the carboxylic acid functions changing the symmetry around the iron atom. Blume⁶

in chemically fixed tissue cultured in vitro7-11 is not an artefact of chemical fixation.

Basal nutrient solution12, modified by replacing sulphuric acid with 0.50 mmoles/l. of ammonium sulphate. was placed in Petri dishes lined with Whatman No. 40 or 42 ashless filter paper and sterilized by autoclaving in special conditions¹³ or by placing them in a deep freeze Vesicle stalks from mature lemon fruits overnight. (Citrus limon (L.) Burmann, variety 'Eureka') were inoculated aseptically onto the nutrient medium and placed in the dark at 25°C. After 24-48 h the stalks were immersed in distilled water in a Petri dish and placed in a deep freeze for 24 h or longer.

The frozen tissue was thawed to room temperature and unstained squash preparations were made as follows. Individual stalks were blotted dry, squashed between two microscope slides without any adhesives and air-dried for 10 min after separating the slides. Isopropyl alcohol was slowly added to the slide near the tissue until the tissue was flooded. After 2 min, the alcohol was drained off and the process was repeated three more times. After the last application of alcohol the tissue was mounted in 'Euparal'. If squashed tissue clung to both slides, both were dehydrated and mounted. A number of stalks were squashed and then mounted directly in corn syrup without any isopropyl alcohol dehydration.

Microscopic examination of the unfixed frozen tissue revealed the characteristic enlarged spherical or pearshaped nucleoli with the prominent inclusions or granules (Fig. 1a) as observed in interphase nuclei of chemically fixed lemon fruit tissue of previous investigations8,10,14. Each of the granules appeared to consist of a refractile body completely enveloped by a ring of contrasting material (Fig. 1a). Between crossed polars these nucleolar inclusions manifested pronounced birefringence with a maltese cross similar to that shown by starch granules in similar conditions, with the direction of maximum refractive index lying tangentially (Fig. 1b). These birefringent granules were orange yellow in colour under white light. Variation of the direction of maximum refractive index as reported for chromosomes15 was not

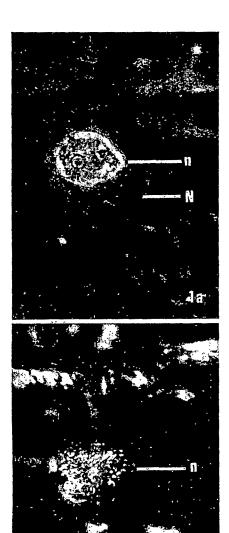

Fig. 1. a, Nucleus (N) and nucleolus (n) of unfixed vesicle stalk after 48 lin vitro showing the prominent nucleolar inclusions. Anoptral phase contrast microscopy. (×1,900.) b, Nucleolus (n) of a viewed between crossed polars showing the birefringent nature of the inclusions. The radial symmetry of many of the granules is obscured as a result of the partial juxtaposition of one granule with another. (×1,600.)

evident in the nucleolar granules, for it remained the same in both unfixed and chemically fixed specimens.

The optically anisotropic nucleolar inclusions described here are clearly not an artefact of chemical fixation. These granules withstand both the strong osmotic changes and disruptive effects of ice crystal formation associated with slow freezing and thawing of cells16 and the physical effects of squashing, and so it is very unlikely that their radial symmetry was brought about by a fixative action of the isopropyl alcohol used for dehydration. The presence of the same symmetrical bodies in nucleoli exposed to such widely divergent treatments as slow freezing and thawing and chemical fixation (CRAF, chrome-acetic, formaldehyde, and alcohol-acetic-formaldehyde fixatives) also makes it extremely unlikely that such a molecular ordering was brought about by a fixative action of isopropyl alcohol. The phenomenon of nucleolar birefringence occurring in unfixed squash preparations mounted in corn syrup without alcohol dehydration provides further evidence that dehydration and not fixation is the primary action of the isopropyl alcohol. The use of unstained squash preparations also precludes the introduction of artefacts resulting from staining reactions or contamination by embedding media such as paraffin inclusions, which have been reported as being responsible for birefringence of nuclei in animal cells17.

The granules in any given nucleolus do not lie in a single plane and seem to be oriented at distinct intervals along a strand or strand-like structure (see especially Fig. 5 of ref. 14). This seems to agree with recent investigations of La Cour¹s concerning the filamentous component (nucleolonemata) of plant nucleoli. He has shown that in a number of plant species studied, the nucleolonemata contained vacuoles along their entire length. It is therefore possible that the birefringent nucleolar granules described here may correspond to the vacuolar regions in the nucleolonemata of the plant species studied by La Cour¹⁸. The chemical and physical nature of the nucleolar material associated with birefringence is as yet unknown. Now, however, that the granules have been found not to be fixation artefacts, the way is open for their cytochemical and biophysical analysis.

This investigation was supported by a Public Health Service research award from the National Cancer Institute, US Public Health Service. We thank W. D. Brain and L. Child for the photographic work.

BIOCHEMISTRY

Relevance of Proton Uptake induced by Light to the Mechanism of Energy Coupling in Photophosphorylation

THE relevance of proton movements which are dependent on energy to energy conservation mechanisms in oxidative phosphorylation and photophosphorylation has recently been extensively debated, particularly with respect to the "chemiosmotic",2 and chemical,4 hypotheses. There are a few critical tests of the chemiosmotic theory. include: (a) the ratio of protons taken up to electrons transported; the value of this H⁺: e⁻ ratio should equal the number of sites of energy conservation in the electron transport path; (b) the effect of phosphorylating conditions; during phosphorylation one should observe a fall in the steady state extent of the proton gradient, as a result of the stoichiometric utilization of one or two protons² per ATP synthesized. Reversible pH changes in spinach chloroplasts induced by light have previously been described in detail^{5,8}. This communication reports experiments designed to test the chemiosmotic theory by these criteria. The results cannot be reconciled with the theory as it is at present conceived.

Figs. 1a and b show the initial rates of uptake of protons and oxygen in a suspension of chloroplasts, using diquat (N,N')-ethylene-2,2'-dipyridilium dibromide) as an electron acceptor. The most relevant experimental value of H^+ : H^+ :

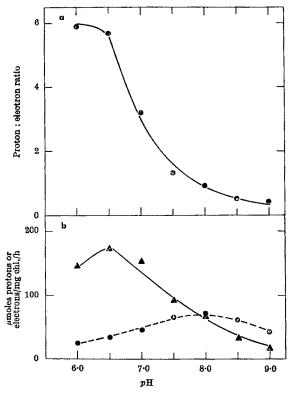

Fig. 1. Effect of pH on initial rates of proton and oxygen uptake, and on the H^+ : e^- ratio. The reaction mixture contained chloroplasts, prepared as previously described, containing chlorophyll 70 $\mu g/ml$.; sodium chloride, 15 mmolar; alquat, 3 μ molar; azide, 0.7 mmolar; pH changes were measured on a Radiometer pH electrode connected to a recorder and were calibrated by addition of a standard acid to the reaction mixture. Oxygen uptake was measured on a Gilson oxygraph. Illumination was with a 500 W slide projector fitted with a 580 $m\mu$ interference filter, of 12 $m\mu$ half-band width. The intensity of illumination was about 1.0×10^5 ergs cm⁻¹ sec⁻¹. a, H^+ : e ratio; b, h—h, H^+ uptake; h—h, electron transport.

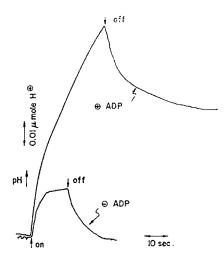

Fig. 2. Effect of phosphorylating conditions on the light-induced proton uptake. The reaction mixture included chloroplasts containing chlorophyll 50 µg/ml.; pyocyanine, 10 µmolar; sodium chloride, 30 mmolar; phosphate, 0.5 mmolar; magnesium chloride, 0.5 mmolar. ADP, 0.2 mmolar, was added where indicated. The pH was 7.8. A 700 mµ interference filter of half-band width 30 mµ was used for illumination. Other conditions as described under Fig. 1.

varies strongly with $p{\rm H}$ and has a maximum value of 6 at $p{\rm H}$ 6.0. The consequent prediction of six coupling sites in the electron transport path to diquat is difficult to accept in the light of current knowledge. It is also difficult to reconcile the observed variation of the ${\rm H}^+$: eratio with a mechanism whereby proton translocation and electron transport are obligatorily coupled. We have observed a similar variation with $p{\rm H}$ and a maximum ${\rm H}^+$: eratio value of four using ferricyanide as an electron acceptor. Values of 5 ${\rm H}^+$: erand 5 ${\rm H}^+$: hy have previously been reported using chloranil and pyocyanine. respectively.

Fig. 2 shows the effect of the complete phosphorylating system on the pH changes. In the absence of ADP, the usual reversible light-induced proton uptake can be observed, but in its presence two phases are seen in the light. The first represents the usual proton uptake and the second represents the irreversible proton consumption accompanying ATP synthesis at pH 8.

$$ADP^{3-} + HPO^{3-} + H^+ \rightarrow ATP^{4-} + H_2O$$

When the light is turned off, the yield of reversible proton uptake which has accumulated during phosphorylation is recorded. Fig. 2 shows that, surprisingly, this yield is greater than in the control curve (-ADP). In Table 1 we show the results of an experiment in which the control curve was attained with ADP, phosphate and 0·1 mmolar EDTA. EDTA at this concentration prevents the low rate of photophosphorylation due to the presence of endogenous magnesium. Increasing rates of phosphorylation can be initiated by addition of increasing concentrations of magnesium chloride. The value of these rates is calculated from the second slope of the full phos-

Table 1. EFFECT OF PHOSPHORYLATING CONDITIONS ON THE LIGHT-INDUCED PROTON UPTAKE

Mg++ concentration	ATP synthesis	Expe Assuming 2H+/ATP	Yield eted Assuming 1H+/ATP	Observed
mmolar	μ moles/h/mg chl.	•	noles H ⁺ /mg chl	•
0	0	0	0	0.13
0∙06	15	0.01	0.08	0.18
0.09	60	-0.01	0.05	0.27
0.16	120	-0.10	0-0	0.38
0.32	200	-0-34	-0.08	0.58
0-64	235	-0.39	-0.11	0.75

The system included chloroplasts containing 60 μ g chlorophyll/ml.; pyocyanine, 12 μ molar; EDTA, 0·1 mmolar; sodium chloride, 16 mmolar; ADP, 0·24 mmolar; phosphate, 0·48 mmolar; and magnesium chloride at the concentrations indicated. The pH was 8·0. Other conditions as in Fig. 1, and illumination as in Fig. 2.

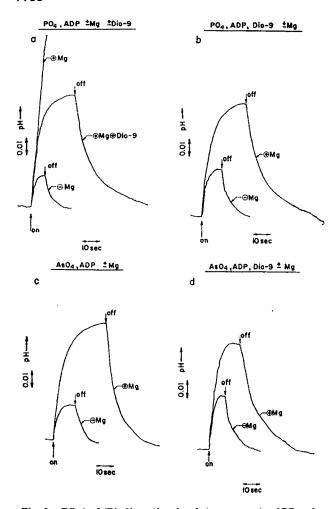

Fig. 3. Effect of 'Dio-9' on the phosphate or arsenate, ADP and magnesium stimulation of light-induced proton uptake. Conditions as in Table 1, except that arsenate or phosphate, 0-5 mmolar, magnesium chloride, 1-0 mmolar, and 'Dio-9', at 4 mg/ml., were added as indicated in the figures. Illumination as in Fig. 2.

phorylation curves, assuming 0.93 protons are consumed for each molecule of ATP formed at pH 7.8 (ref. 9). The higher the rate of ATP synthesis, the larger the steady state extent of proton uptake into the chloroplasts. Also shown are calculations of the yield which is expected on the basis of the chemicsmotic theory, assuming that one or two protons are utilized from the gradient per ATP synthesized. The calculations are based on a simple kinetic model of the light-induced proton uptake and we are now preparing the manuscript. The rate of ATP synthesis was increased to a point at which negative values of the yield of proton uptake were predicted. In other words, in such phosphorylating conditions the observed rate of proton uptake is insufficient, according to the chemicsmotic theory, to support the observed rate of ATP formation.

The combination of arsenate, ADP and magnesium was previously shown to "uncouple" photophosphorylation 10 , but unlike other uncouplers, this combination was found to increase the extent of proton uptake rather than inhibit it (Table 2). Stimulations of four-fold over the control value have been observed. The pH optimum of the stimulation was pH 8.2.

Fig. 3 shows the effect of the energy-transfer inhibitor 'Dio-9' on the pH changes induced by light in the presence of phosphate or arsenate, ADP and magnesium. Fig. 3a illustrates that the addition of 'Dio-9' to a complete phosphorylation system (+Mg), at a concentration which totally inhibits ATP synthesis (that is, the irreversible proton uptake), does not eliminate the increase in the steady state proton uptake induced by the phosphorylation system. This striking observation is re-emphasized

Table 2. EFFECT OF ADP, ARSENATE AND MAGNESIUM ON LIGHT-INDUCED PROTON UPTAKE

Reaction mixture	Yield μ moles H+/mg chl.
Control Plus Mg Plus Mg, arsenate Plus ADP, arsenate Plus Mg, ADP Plus Mg, ADP, arsenate	0·12 0·12 0·13 0·11 0·14 0·32

The system included chloroplasts containing 50 μg of chlorophyll/nl.; pyocyanine, 12 μ molar; EDTA, 0·1 mmolar; sodium chloride, 16 mmolar; ADP, 0·24 mmolar; arenate, 0·25 mmolar; and magnesium chloride, 1·0 mmolar, where indicated. The pH was 7·8. Other conditions as in Fig. 1, and illumination as in Fig. 2.

in Fig. 3b, where 'Dio-9' is included in the control (-Mg). Subsequent addition of magnesium chloride still produces a large increase in the steady state yield of proton uptake. It may be noted that in these conditions (pH 8) 'Dio-9' increases somewhat the usual (-Mg) proton uptake. In Figs. 3c and d, it can be seen that the same basic phenomena occur when arsenate replaces phosphate. Thus 'Dio-9' at a concentration which completely inhibits ATP synthesis does not markedly affect the stimulatory effect of arsenate, ADP and magnesium on the steady state proton uptake.

The finding that, in the presence of a complete phosphorylating system, the yield of light-induced proton uptake is higher than in its absence contradicts both the chemiosmotic and chemical theories. Both theories, as put foward at present^{2,4}, assume an equilibrium between ion transport and a non-phosphorylated high energy intermediate. In the former, the proton gradient is coupled to electron transport and gives rise to " $\sim X$ ", while in the latter the proton gradient is the result of "~X". The observed increase in proton uptake in the presence of arsenate or phosphate, ADP and magnesium could be interpreted as representing the sum of two processesproton efflux stoichiometric with ATP formation, as required by the chemiosmotic theory, together with a second proton accumulating process. The calculations in Table 1, however, make it unlikely that there is a sufficient rate of proton uptake in the control sample to support the observed rate of ATP synthesis as demanded by the chemiosmotic theory.

We were prompted by these observations to consider a model in which the prime function of the proton pump is to enable co-transport into the chloroplast of a negatively charged complex of HPO?—or HAsO?—Mg³+ and ADP³-(see Fig. 4). The increase in proton uptake observed in our case with arsenate or phosphate, ADP+Mg present, is a result of the fact that these are the "natural substrates" of the ion transport system and thus permit a higher activity than other "substrates" with a lower affinity, such as chloride. This co-transport may be of an effec-

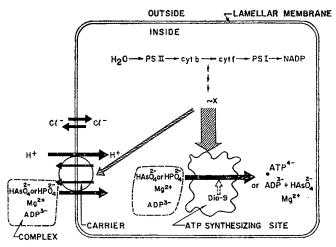

Fig. 4. A hypothetical model describing the proposed function of light-induced proton uptake in chloroplasts; see text for details.

tively uncharged complex of protons and HPO, Mg2+ and ADP3-. It has previously been shown that the uncharged species of several weak acids is that which best penetrates passively into the chloroplasts¹¹.

The model envisaged in Fig. 4 allows protons and a phosphate or arsenate, magnesium and ADP complex to be simultaneously transported on the same or different "carrier" proteins. ATP or ADP+AsO₄ will be formed subsequently on an ATP synthesizing enzyme complex. 'Dio-9' has been shown to inhibit the induced ATPase of the EDTA extracted coupling factor¹², and is therefore assumed to act at the ATP synthesizing site. The experiments shown in Fig. 3 are consistent with the hypothesis presented, which allows the arsenate or phosphate, ADP, and magnesium effects to lie before the site of action of 'Dio-9' (that is, on a carrier in our hypothesis, Fig. 4).

Finally, it must be remarked that the hypothesis requires that the actual energy expenditure in transporting the phosphate or arsenate, ADP, magnesium complex is a small fraction of that involved in the subsequent ATP synthesis reaction. 'Dio-9' has been shown to inhibit the uncoupling of photophosphorylation caused by arsenate ADP and Mg (ref. 12). Hence no significant uncoupling of photophosphorylation (that is, stimulation of electron transport) can be envisaged as occurring as a result of the energy expenditure involved in the arsenate or phosphate, ADP+magnesium, uptake process.

Disappearance of Ribosomes and Polyribosomes during in vivo **Erythroid Maturation**

Burka and DeBellis¹ have compared the disappearance of ribosomes and polyribosomes during in vivo erythroid maturation in the rabbit. In order to study in vivo maturation of circulating erythroid cells labelled with isotope, unobscured by the continued release of new cells from the marrow, they injected labelled cells from a donor animal into a lethally irradiated recipient which continued to receive colchicine. In contrast to previous work² which they cite on this subject, they failed to find a disproportionate loss of polyribosomes and an increasing proportion of single ribosomes during maturation.

They provide sucrose density gradient patterns (Fig. 1, top) as evidence that the proportion of polyribosomes is

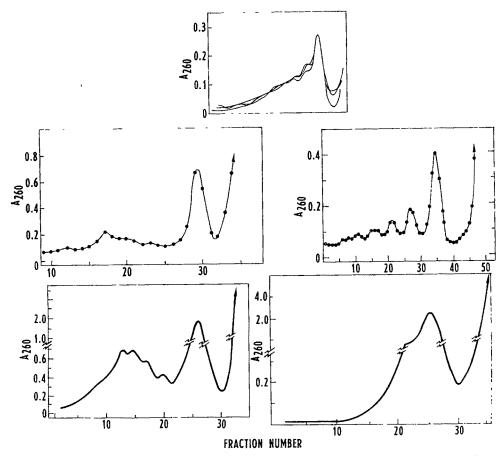

Fig. 1. Sucrose gradient analyses of ribosomal composition of rabbit reticulocyte lysates. (The ordinate scales have been adjusted to facilitate comparison.) Top: From Burkai. The individual lines represent profiles obtained 15 min, 1 h and 5 h, respectively, after reticulocyte infusion. Middle: From Warner et al.². Left, native; right, degraded. Bottom: From Elkenberry et al.³. Left, control; right, ribonuclease treated.

constant as a function of time. These, however, resemble the patterns obtained for partially degraded polyribosomes by Warner, Knopf, and Rich3 (Fig. 1, right centre) or those obtained by the addition of ribonuclease (Eikenberry and Rich4, Fig. 1, bottom right), rather than those density gradient patterns for polyribosomes in the native state (centre and bottom, left). In the gradient profiles of Burka there are more aggregates of two ribosomes than of three, more aggregates of three than of four, and more aggregates of four than of five, whereas the native lysate contains more aggregates of five ribosomes than aggregates of four, three or two ribosomes. In view of the possibility of degradation in the patterns of Burka, one might conclude that the similarity in his patterns as a function of age simply represents degradation to a uniform state. Metabolic Effects of Methionine in Schizophrenic Patients pretreated with a Monoamine Oxidase Inhibitor

ORAL administration of a large amount of methionine to schizophrenic patients who had been treated with a monoamine oxidase inhibitor (MAOI) was reported to produce psychic symptoms which have been interpreted either as an intensification of schizophrenic symptoms or as superimposed toxic symptoms 1-4. The effects of methionine and MAOI have been explained as an increase in the amounts of methylated amines, such as bufotenin, N,N-dimethyltryptamine, 3,4-dimethoxyphenylethylamine or unknown amines which have been claimed to be psychotogenic substances. One of the purposes of the present experiments is to determine whether methionine increases the rates of N or O-methylation of catechol and indolic amines.

Asao and Yamano have re-investigated the clinical effects of MAOI and methionine. Eight hospitalized Eight hospitalized schizophrenic females aged between 31 and 57 who had the disease for more than 13 yr were selected. Treatment was stopped during the experimental period. Isocarboxazid (1 mg/kg/day) was administered in three divided doses from the eighth day of the experiment for 2 weeks, and 0.3 g/kg/day of L-methionine was given in three divided doses from the fifteenth day for I week. The symptoms observed were different from those characteristic of schizophrenia, but were the superimposed symptoms of intoxication such as delirium, visual hallucination, ataxia, speech disturbance, increased salivation and hyperhidrosis. Urine specimens (24 h) were collected on days 6, 7, 13, 14, 20, 21 and 30 in a bottle containing 200 ml. of isopropyl alcohol and 0.5 g of ethylenediamine tetraacetate (EDTA), and frozen until analysed.

A sample of urine containing 600 mg of creatinine was partially purified by the method of Kakimoto and Armstrong⁵, then dried eluate from a column of 'Dowex 50' was dissolved in 5 ml. of water, applied to a 2×4 cm column of 'Amberlite CG-50', diethylamine form, the resin was washed with 40 ml. of water and the amines were eluted with 40 ml. of 3 normal ammonia. The dried eluate was dissolved in 3 ml. of 70 per cent ethanol, passed through a column of 2.5 g of alumina suspended in ethanol and the column was washed with 15 ml. of 70 per cent ethanol. The total effluent was combined and the dried residue was dissolved in 90 per cent ethanol, and three equal portions were applied to three sheets of Toyoroshi No. 51 which is of a similar quality to Whatman No. 1. The recovery rates of normetanephrine and serotonin added to urine were greater than 70 per cent. One chromatogram was developed with solvent systems consisting of a mixture of isoamylalcohol, acetic acid and water (60:27:15) for the first dimension and a mixture of n-butanol, pyridine and 3 normal ammonia (50: 25: 20) as the second. The other two chromatograms were developed with the same solvent systems as used by Kakimoto and Armstrong⁵. The paper chromatogram developed with the first two solvent systems was visualized with ninhydrin, and the other two chromatograms with the diazotized p-nitroaniline and with Ehrlich reagent for phenolic and indolic amines, respectively.

Seventeen ninhydrin positive compounds were constantly observed, but the chromatograms were unchanged after treatment with isocarboxazid and methionine. 3,4-Dimethoxyphenylethylamine^{6,7} was not found in any urine specimens. Paper chromatograms of phenolic and indolic amines showed that the intensities of the amines did not change significantly after the loading of methionine under the influence of the MAOI, and the compounds which suggest accelerated formation of N-methyl amines were not found. From the rate of recovery of bufotenin and N-methyltryptamine when added to urine, daily amounts of these amines should be less than 10 µg, if they occurred. Failure to detect other N-methylated amines such as N-methylserotonin, bufotenin, N-methyltryptamine and N,N-dimethyltyramine after loading with methionine does not support the hypothesis that methionine exerts its action through increased methylation.

If methylation is stimulated by methionine, catecholamines should be methylated at an increased rate in the body and the amounts of normetanephrine and metanephrine should increase more intensely than noradrenaline and adrenaline. Adrenaline and noradrenaline were determined by a modification of the method of Von Euler Eluate from an alumina column was and Floding⁸. passed through a 0.3×1.0 cm column of a freshly prepared acetate form of 'Dowex 1', and the effluent was assayed fluorimetrically⁸. The introduction of the step with 'Dower 1' could remove the interfering substances described by Berlet et al.4, who reported difficulty in assaying catecholamine in the urine of subjects with methionine loading. Metanephrine and normetanephrine were measured by the method of Taniguchi et al.³. When methionine was administered to the patients under the influence of MAOI, the amounts of these four amines increased, but the ratio of the amount of metanephrine to that of adrenaline and the ratio of normetanephrine to noradrenaline did not rise, suggesting that the O-methylation of catecholamines was not accelerated by loading with methionine. These results are shown in Table 1.

For the determination of amino-acids an amount of concentrated urine corresponding to 1 mg of creatinine was applied to a Toyoroshi No. 50 which is of a similar quality to Whatman No. 3 MM. Chromatograms were run two-dimensionally with solvent systems devised by M. D. Armstrong of the Fels Research Institute, Yellow Springs, Ohio. The first solvent system is a mixture of pyridine, acetone and 3 normal ammonia (50:30:25) and the second one is a mixture of isopropylalcohol. formic acid and water (8:1:1). The paper was dipped in an 0.2 per cent ninhydrin solution in acetone, acetic acid and pyridine (18:1:1) and heated at 90° C for 3 min. Coloured areas of amino-acids were cut, eluted with 5 ml. of 50 per cent ethanol and the solution was assayed colorimetrically at 570 mu. The chromatographic pattern of urinary amino-acids was not changed by the administration of isocarboxazid, but was changed markedly after the loading of methionine in all eight individuals. The change in the intensities of the spots was not confined to methionine and its metabolites such as cystathionine and methionine sulphoxide, and greater changes were observed in a few other amino-acids. The amino-acids, which increased markedly (two- to sixfold) were serine, threonine, glutamine and histidine. The result was further confirmed by determination with an amino-acid analyser, which showed increases in the amounts of these amino-acids and These findings may reflect a disturbance of the metabolism or membrane transport of the amino-acids.

The identities of cystathionine and methionine sulphoxide were confirmed by the isolation of the compounds followed by the comparison of their infrared spectra with the authentic amino-acids. The spectrum of the isolated cystathionine coincided with that of L-cystathionine but not of L-allocystathionine. The spectrum of the isolated methionine sulphox. Je coincided completely with that of L-methionine-d-sulphoxide, but different from the l-sulphoxide. The authentic compounds were prepared by the method of Lavine¹⁰. This indicates that the sulphoxide found in urine is formed by an enzyme in a stereospecific

Table 1. Amounts of adrenatine, noradrenatine, metanephrine and normetanephrine in trine

	,	None	Isocarboxazid	Isocarboxazid +methionine
Adrenaline Noradrenaline Metanephrine Normetanephrine Metanephrine/adrenaline* Normetanephrine/noradrenaline*		4·8 (3·2) 20·0 (9·3) 7·6 (4·0) 11·7 (3·9) 2·1 (1·2) 1·3 (1·6)	3·1 (1·3) 12·4 (7·3) 10·3 (5·6) 27·1 (7·5) 3·3 (1·1) 3·4 (2·1)	8·8 (6·3) 25·6 (22·1) 18·2 (9·6) 36·9 (17·4) 2·6 (1·3) 2·1 (1·3)

Numbers not in parentheses represent the mean of the amounts of amines in two 24 h urine specimens from eight patients (μ g/g of creatinine), and numbers in parentheses are standard deviations. None, isocarboxazid, and isocarboxazid+methionine represent experimental periods of 0 and 7, 13 and 14 and 20 and 21 experimental days respectively.

* Mean of the ratios of the amount of a 3-0-methylated amines to that of its precursor amines in each urine specimen.

manner, and is not an artefact formed from methionine by spontaneous oxidation. The occurrence of methionine sulphoxide in large quantities in urine (2·7 μmoles/day on average) is interesting from the point of view that the sulphoxide has been thought to play a pathophysiological part in hepatic coma¹¹. Amounts of free sulphate were 7.1 ± 1.9 and 79 ± 24 mmole/day before and after methionine loading respectively. These results suggest amino-acid imbalance and ionic disturbances under the influence of methionine, and these may have to be taken into consideration before the psychic effects of methionine can be understood.

We are indebted to Dr Asao, Dr Yamano and the nurses of Osaka Prefectural Nakamiya Hospital for collecting urine specimens.

Possible in vivo De-acetylation of N-Acetylhistamine in Man

AUTHENTIC N-acetylhistamine is degraded by human faeces in vitro and a histamine-like activity concurrently evolves, so the underlying mechanism for the decay seems to be de-acetylation.

The so-called conjugated histamine in urine consists solely or partly of N-acetylhistamine². The only observations on in vivo stability of conjugated histamine have been carried out on dogs by Anrep et al.3. After subcutaneous administration, conjugated histamine could be recovered almost quantitatively from the urine, but in these experiments unphysiologically high dosages of conjugated histamine seem to have been used. I have now examined the fate of small quantities of parenterally administered N-acetylhistamine in man.

N-Acetylhistamine (Calbiochem) was dissolved in isotonic saline, and the solution was sterilized by heating or by sterile filtration. A portion of the sample was subjected to two-dimensional paper chromatography1, and biological assay for free histamine and N-acetylhistamine, the latter after acid hydrolysis. There was no evidence of decay of the N-acetylhistamine before administration.

N-Acetylhistamine (205-37,000 µg, calculated as the base) was injected subcutaneously (twelve experiments on four healthy individuals). No untoward sympon four healthy individuals). No untoward symptoms followed the injections. Urine was collected for 24 h in bottles containing 100 ml. of 1·2 normal hydrochloric acid and the amount of histamine in the urine was estimated as described by Dunér and Pernow4. Mean recoveries of small amounts of histamine diphosphate (Nutritional Biochemicals Corporation) and Nacetylhistamine added to urine were 72 ± 8.3 (S.D.) and 74 ± 8.6 per cent, respectively. The mean urinary excretion of free histamine (unweighted values) in a control series was 12.6 ± 0.9 (standard error of mean), and the range 2-31 µg base/24 h. The corresponding values for conjugated histamine were 30.0 ± 5.9 and 1-99 (ref. 5).

The results are presented in Table 1. No corrections for losses during the procedure have been made for the urinary excretion of free and conjugated histamine. The recoveries of N-acetylhistamine in urine, however. have been calculated from corrected values.

It is evident that only a fraction of the administered dose of N-acetylhistamine is excreted unchanged in the The mean percentage not recovered with urine in 24 h.

doses of less than 224 μg of N-acetylhistamine was 62 ; with doses of more than 7,000 μg the corresponding figure was 46. The ratio of excretion at 6 h to that at 24 h makes it unlikely that appreciable excess excretion of conjugated histamine takes place after 24 h.

Only 2-3 per cent of histamine administered parenterally to healthy individuals is excreted unchanged in the This may explain why there was no definite increase in the free fraction in the urine in experiments with small doses of N-acetylhistamine. With larger doses, an increase in urinary output of free histamine was found (P < 0.05, both with hypothesis null andStudent's t test). There are at least two feasible explanations for these findings: (I) the mechanism could be that of a de-acetylation of N-acetylhistamine; (2) the administered N-acetylhistamine could hinder the catabolism of endogenous histamine along the N-acetylhistamine pathway by product inhibition. The second possibility seems unlikely for the following reason. If a quantitatively rather unimportant pathway of histamine catabolism, such as acetylation, is blocked, the more important histamine-degrading enzymes that is, histaminase and the methylating enzymeshould be able to handle the small extra quantity of histamine. If this were the mechanism, the free fraction in urine should not increase. De-acetylation therefore seems to be the most likely explanation for the present observations.

It may seem peculiar that N-acetylhistamine is excreted unchanged to a higher extent when ingested, even in small doses7, than when administered parenterally. It seems reasonable, however, to assume that this depends on one of the following mechanisms: either orally administered N-acetylhistamine is conveyed through fluids and tissues with a relative lack of the de-acetylating system, or N-acetylhistamine is protected against deacetylation by some sort of binding.

These observations may necessitate a reappraisal of the supposed unimportant role allotted to acetylation in the catabolism of histamine6,8.

It would also be interesting to investigate whether N-acetylhistamine and histamine are formed from Nacetyl-L-histidine in vivo as they are in faecal specimens with a high capacity to form histamine1.

Molecular Weight of Human Follicle Stimulating Hormone

FOLLICLE stimulating hormone (FSH) was obtained from powdered human pituitary dried with acetone and purified in two ways: (a) by the method of Amir, Barker, Butt and Crooke¹, and (b) by the cellosolve extraction procedure of Butt, Crooke and Wolf² followed by fractionation on DEAE-'Sephadex A-50'. Haemagglutination inhibition tests showed that luteinizing hormone (LH) and albumin were present to an extent of less than 1 per cent by weight of protein. FSH obtained by both procedures seems to undergo reversible association and dissociation, as the following experiments show.

The material gave two peaks when chromatographed on a column of 'Bio-Gel P-30' (22 \times 1-6 cm) in 0-01 molar phosphate buffer, pH 7.1 (Fig. 1A), the first peak being totally excluded (molecular weight greater than about The position of the second peak suggests a 30,000). molecular weight of 16,000-17,000 when compared with the elution diagrams for a-chymotrypsin (molecular weight 23,000), ribonuclease dimer (25,400) and ribonuclease monomer (12,700), assuming that the relationship log_{10} (molecular weight) = k (elution volume) holds for this column within the appropriate range. Chromatography on 'Bio-Gel P-100' (17×1 -6 cm) gave three peaks (Fig. 1B). The first peak was totally excluded, representing a molecular weight of greater than about 55,000. The third peak was totally included and thus represents material of molecular weight less than 20,000. The position of the second peak implies a molecular weight of approximately 34,000 by comparison with carboxypeptidase A (34,500) which was eluted in a similar position. On 'Bio-Gel P-150' (20 \times 1.6 cm) two peaks were obtained, the second being totally included as expected (molecular weight less than 50,000). The position of the first peak was the same as that of albumin, which indicates a molecular weight of about 68,000 (Fig. 1C).

The material thus seems to be a mixture of three species with molecular weights of approximately 68,000, 34,000 and 17,000. When a solution of FSH in the buffer was made I molar in sodium chloride, stored for several hours

—, FSH; ---, FSH after treatment with 1 molar sodium chloride.

a, Position at which blue dextran was eluted; b, ribonuclease dimer (molecular weight, 25,400); c, chymotrypsin (molecular weight, 23,000); d, ribonuclease monomer (molecular weight, 12,700); e, salts. B, 'Bio-Gel P-100'.

—, FSH; ---, FSH after treatment with, and subsequent removal of, sodium chloride. f, Blue dextran; g, carboxypeptidase (molecular weight, 34,500). C, FSH on 'Bio-Gel P-150'. h, Blue dextran; j, albumin (molecular weight, 68,000).

at 0° C and then chromatographed on the 'Bio-Gel P-30' column, a single peak was obtained which corresponded to a molecular weight of 16,000-17,000 (Fig. 1A).

The peak from the 'Bio-Gel P-100' column which corresponded to a molecular weight of 34,000 was concentrated to 1 ml. by ultrafiltration, made 1 molar in sodium chloride and, after several hours, was chromatographed on the 'Bio-Gel P-30' column, giving a single peak again corresponding to a molecular weight of 17,000. When this peak was again concentrated to approximately 1 ml. (the sodium chloride having been removed during the chromatography) and rechromatographed on the 'Bio-Gel P-100' column, it gave a major peak at molecular weight 34,000 and a minor one totally excluded (Fig. 1B). The peak and a minor one totally excluded (Fig. 1B). The peak corresponding to a molecular weight of 68,000 from the 'Bio-Gel P-150' column underwent the same interconversions (that is, to molecular weight 17,000 in 1 molar salt and then to 34,000 on removal of the salt), as also did the first and third peaks from the column of 'Bio-Gel P-100'. When the preparations were stored in the absence of sodium chloride, those which showed single peaks of molecular weight 34,000 were converted into mixtures containing the two higher forms. The original preparations of FSH which contained all three forms had been obtained by chromatography using elution with salt gradients, and, on prolonged storage after dialysis, these were converted principally into the high molecular weight form.

Thus FSH apparently exhibits association and dissociation according to the salt concentration of the medium; in 1 molar salt the molecular weight is about 17,000 and in 0.01 molar phosphate buffer association occurs giving dimeric and tetrameric forms. No evidence of the presence of a trimer was observed. The association dissociation process seems to have no effect on the biological activity of the hormone; peaks corresponding to all three molecular weight forms were active in the ovarian augmentation assay.

This observation agrees well with data reported previously. Butt, Crooke and Cunningham³ have estimated the molecular weight as approximately 68,000, based on ultracentrifuge-sedimentation measurements, and Odell, Swain and Nydick⁴ have used a radiation-inactivation technique to obtain an average value of 31,400 (30,000–34,000). Li and Starman⁵ have demonstrated the phenomenon of dissociation in another gonadotrophin, luteinizing hormone, which apparently has a monomer form of molecular weight 16,300.

I thank Professor M. Stacey for his interest and Dr S. A. Barker of this department and Drs W. R. Butt and A. C. Crooke of the United Birmingham Hospitals for their helpful discussions. The work was supported by a block grant from the Medical Research Council.

Nucleotide Rhythms in the Mature Rat Heart

CARDIAC cells in adult humans or animals, like neurones, do not divide in the mature state¹, in contradistinction either to cells which continue to proliferate throughout the life of the organism (haematopoietic, oesophago-intestinal cells), or which show a gradual waning of this capacity with maturity (liver)². Mitotic figures have been seen in certain human infant hearts but these cases are rare and serve as exceptions to the rule.

Pelc^{1,3}, in a study of DNA synthesis in the rat heart, demonstrated the incorporation of tritiated thymidine into cardiac cells in an amount deduced to be eight to twelve times greater than that needed for cell division. The administration of 'Colcemid', followed by killing and autoradiographic examination of heart muscle, revealed no labelled divisions after 49 h, 73 h or 7 days. Pelc suggested that such incorporation of thymidine, as indicative of DNA synthesis, implies either DNA metabolism and turnover or a progressive movement towards a hyperdiploid cell. Such cardiac hyperdiploid cells have been well demonstrated in human cardiac hypertrophy³.

Our approach to a study of biochemical synthesis in the heart has been to observe rhythmicity in certain chemical components of the cardiac cell. We used 6 month old Sprague—Dawley male rats which had been conditioned on a 12 h lighting regimen and fed a standard laboratory diet from time of weaning. The hearts were removed from groups of six at 0800, 1500, 2000 and 2400 h. The atria were removed, the blood blotted off and the remaining entire ventricular myocardia frozen until individually analysed for protein and the nucleic and free amino-acids by methods described by Wannemacher et al.⁵ and Squibb⁶.

Table 1. BODY AND HEART WEIGHTS AND TOTAL CONTENT OF DNA

Hours	0800	1500	2000	2400
Heart weight (g)	0.836*	0.751	0.725	0.719
Body weight (g)	337*	312	312	309
Heart weight/body weight	0.0025	0.0024	0.0023	0.0024
Total DNA (mg)	1.04	0.94	0.99	0.90*

^{*} Significance at 5 per cent level.

The average heart weight of the rats was greater at 0800 h (P < 0.05), and the ratios of heart-body for the periods sampled averaged 0.0025, 0.0024, 0.0023 and 0.0024, respectively (Table 1). The biochemical results, shown in Fig. 1, demonstrate a definite rhythm for DNA (P < 0.05), RNA (not significant), total protein (P < 0.05)

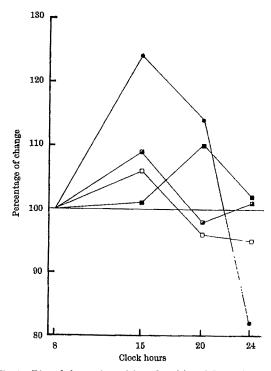

Fig. 1. Diurnal changes in protein and nucleic and free amino-acids in the mature rat heart.

DNA; , RNA; , protein; , free amino-acids.

and free amino-acids (P < 0.05). Furthermore, they delineate a period of an increase in DNA synthesis which, although it covers a span of 9 h, in all likelihood could be narrowed somewhat by more numerous within-period samplings. When the total quantities of DNA are calculated (heart weight \times mg of DNA/g wet tissue) an actual diurnal change in cellular DNA can be seen, with quantities significantly (P < 0.05) lower at 2400 h (Table 1). Increases and decreases in DNA synthesis in each gram of tissue have been noted in seminal vesicles1 and in chick livers, and intestines (Squibb, unpublished results). Total DNA (in mg) in relation to the heart-body weight ratio demonstrates an absolute change in quantities of this nucleic acid. This would suggest a diurnal rhythm which is the result of an increased synthesis of DNA apparently unrelated to the production of new cardiac cells. No determinations of ventricular water content were made in this experiment, but previous analyses by other investigators have revealed a constant diurnal water content for liver and heart⁸⁻¹⁰. We have analysed chicken liver every 4 h over a period of 48 h in controlled diurnal experiments and found a 1 per cent variation in liver cells with a water content of 70 per cent (unpublished results).

The curves in Fig. 1 indicate there was an accumulation of RNA, total protein and free amino-acid which preceded and partially continued into the zone of early DNA increase. It has been demonstrated11,12 that DNA, RNA and protein synthesis is integrated, with in fact a doubling of DNA, total RNA and cell mass (total protein) before cell division. Our analyses on virtually the entire cardiac ventricular mass, and the lack of any data on what percentage of the cardiac cells is involved in these processes, do not allow such an oversimplification. The data show the free amino-acid pool to be highly dynamic in cardiac tissue, having a distinct diurnal rhythm. We would speculate that changes in these free amino-acid levels relate to protein production as manifested in the protein pattern.

A number of investigators, unaware of this DNA rhythm, have used the nucleotide RNA/DNA relationship between experimental and controlled animals as key data for certain hypotheses. Such workers must now consider the point in diurnal time for the normal and abnormal rhythm.

IMMUNOLOGY

Synthesis of the Antigens of Influenza Virus in Chick Embryo Kidney Cultures as studied by Fluorescent Antibody Techniques

The production of S and V antigens of influenza virus has been widely studied $^{1-6}$. We have investigated the accumulation of influenza virus in susceptible tissue cultures by both the direct and indirect fluorescent antibody techniques and the S and V antigens were simultaneously detected by the indirect method.

Tissue cultures were prepared from the kidneys of chick embryos 18 days old by the method described by Lippelt and Mannweiler and monolayers were grown on tube walls and on cover slips. Cultures were inoculated with 104 or 106 EID₅₀/ml. of influenza A2 virus (strain 2226). After 90 min the cultures were washed twice with Hanks solution, maintenance medium was added and they were incubated at 37° C.

The virus infectivity of the culture medium was studied at intervals by inoculating ten-fold dilutions into the allantoic cavity of 10 day old chick embryos. At the same time the haemagglutination titre was measured by a standard method. Cover slip preparations were dried, fixed in acetone for 10 min and then stained in one of the following ways: (1) direct Coons technique using the globulin fraction of a type-specific anti-influenza horse serum conjugated with fluorescein isothiocyanate; (2) indirect method using the unconjugated globulin of the same serum and a rabbit anti-horse conjugate; (3) indirect method using specific antisera to S and V antigens (given by Drs Vonka and Zavadova of the Serum and Vaccine Institute, Prague) and rabbit anti-guinea-pig conjugate.

Standard methods were used to prepare and purify the conjugates8,9 and to stain the preparations and controls.

Table 1. Characteristics of the infectivity of influenza virus produced in cultures of chick embryo kidney at different multiplicities

Multiplicity		tious act EID_{50}/r		Haen activit	ID/HA		
(EID_{60}/cell)	24 h	48 h	72 h	24 h	48 h	72 h	
5.0-10.0	5.25	4.0		1.1	1.2	1.1	4.15
0.05-0.1		6.33	6-0		1.1	1.0	5-23

Table 1 shows the results of the titrations of the infectivity and haemagglutinating activity. It can be seen that the use of high multiplicities (5-10 EID₅₀/cell) leads to the production of a virus population with a relatively lower infectivity than does the use of 0.05-0.1 EID 50/cell.

Immunofluorescent studies with anti-S serum and high multiplicities showed that specific fluorescence first appeared in the nucleus after 4 h. The brilliance of fluorescence increased after 5 h and more fluorescent nuclei were detectable (Fig. 1). After 6 h, S antigen appeared in the perinuclear cytoplasm. By 8-10 h there was fine granular fluorescence throughout the cytoplasm while nuclear fluorescence became gradually weaker (Fig. 2).

Cultures infected with the same dose of virus were stained for V antigen and after 5 h showed diffuse perinuclear fluorescence which spread gradually towards the periphery of the cell and by 8 h included the whole cytoplasm. There was no V antigen in the nucleus.

The appearance and localization of the S and V antigens in preparations inoculated with 10^4 EID_{50} were similar to those in preparations inoculated with 10^6 EID_{50} , but the first fluorescence was observed later (Table 2). The brilliance of nuclear fluorescence was the same after both inocula.

The character and dynamics of appearance of the nuclear and cytoplasmic fluorescence were very similar when antiserum against whole virus and the indirect method were used. Using this antiserum and the direct

Table 2. DYNAMIOS OF THE REPRODUCTION OF INFLUENZA A VIRUS IN CULTURES OF CHICK EMBRYO KIDNEY BY MEANS OF DIRECT AND INDIRECT FLUORESCENT ANTIBODY STAINING

10°	5.0	4 h+				4 h+		*****	-
		5 h++			5 h+	5 h++	5 h+		5 h+
			6 h+ 8 h++		01		6 h+++		6 h + +
101	0.05	6 h+			8h++			4.1.	8 h+++
10-	0.09					6 h+	6 h+	6 h+	
		8 h + + +	8 h + +		8 h +	gh + +	8 h + + +	8 h + + +	8 h + +

method the same sequence of fluorescence was observed after low multiplicities of infection, but after high multiplicities (5.0 EID₅₀/cell) intranuclear fluorescence was not found during the earliest periods, and the specific fluorescence appeared in the perinuclear cytoplasm (Fig. 3).

The data show that using different multiplicities of infection we obtained virus with different levels of infectivity and these results agree with those of others who have used influenza virus and tissue cultures2,8,10. There were no differences in the dynamics of accumulation of S and V antigens with the two multiplicities; this supports the data of Sugiura⁸ and Fraser¹, who found identical appearances in complete and incomplete and in complete and

abortive cycles of reproduction, respectively. This implies that qualitative differences in the nucleoprotein component of the virus do not show themselves in the immunofluorescent picture.

On the other hand, our results differ from those of some authors who have detected in incomplete virus production either diminished production of S antigen^{2,5} or delay in its appearance in the nucleus⁴. This difference may be associated with the slight degree of incompleteness of the influenza virus we used.

The localization and appearance of influenza virus antigen in cells depend on many factors¹¹. We consider that the absence of nuclear fluorescence in incomplete virus production examined by the direct fluorescent antibody method can be explained either by the lesser sensitivity of the direct as compared with the indirect method. by inhibition of intranuclear fluorescence or by a reduction in the titre of the antibody against S antigen during the preparation and purification of the conjugate. In any case it seems that apparent differences between the results of earlier authors could be a reflexion of minor differences in the immunofluorescent technique used.

Maternofoetal Transfer of γ G Immunoglobulins

Brambell has suggested that the mechanisms which underlie the transmission of antibodies and other plasma proteins from mother to foetus are similar to those which operate in the catabolism of these proteins. This concept was supported by the observation that maternofoetal transfer of homologous and heterologous γG globulins in the rabbit decreased with the half lives of these proteins; the species order of decreasing maternofoetal transmission and decreasing half life in the rabbit was rabbit > man > ginea pig > horse > bovine. In this study, the maternofoetal transfer of γG globulin was examined in the mouse, rat and guinea-pig.

Human serum albumin, human γG globulin and bovine γG globulin were obtained by low temperature ethanol-water fractionation^{4,5}, and labelled with iodine-125 by a modification of the nitrous acid method⁶; mouse, rat and guinea-pig serum γG globulins were isolated by means of DEAE-cellulose column chromatography⁷, and labelled⁶ with iodine-131. Of the total radioactivity in each of the labelled protein preparations, more than 98 per cent was precipitable in 10 per cent trichloroacetic acid, and 88–99 per cent was precipitable with specific rabbit antisera

against the unlabelled proteins.

Albino rats, smooth haired guinea-pigs and albino mice were used; all were pregnant and near term. Their drinking water contained 250 mg per cent of sodium iodide beginning at least 24 h before injection of labelled protein to inhibit thyroidal uptake of radioiodine. Each animal was given one of the following labelled protein mixtures, intravenously in the mice and rats and intracardially in the guinea-pigs: mouse $\gamma G^{-125}I$ and human albumin⁻¹³¹I, guinea-pig $\gamma G^{-131}I$ and human $\gamma G^{-125}I$, guinea-pig $\gamma G^{-131}I$ and bovine $\gamma G^{-125}I$, or rat $\gamma G^{-131}I$ and human $\gamma G^{-125}I$. The total labelled protein injected into each animal was less than 0·1 mg for a total of 1-2 μc. The animals were anaesthetized 24 h later, bled, and samples of serum were precipitated in 10 per cent trichloroacetic acid. The guinea-pig and rat foetuses were bled in situ by section of the axillary blood vessels; serum from the foetuses of a given litter were pooled and samples were precipitated in 10 per cent trichloroacetic acid. The mouse foetuses of a given litter less the placentas were weighed, then homogenized in 10 per cent trichloroacetic acid and the final volume was adjusted to 200 ml.; the concentration of labelled protein in foetal serum was determined as the amount of radioactivity for that amount of protein in each g of mouse foetus divided by the average volume of distribution⁸ for human $\gamma G^{-125}I$ which was determined All trichloroacetic acid precipitates were washed twice with a 10 per cent solution of the acid. Assay for iodine-125 and iodine-131 was carried out with a 400 channel spectrometer in conjunction with a 3 in. well type crystal of sodium iodide, each channel being 10 keV in width.

The concentration, F, of labelled protein in foetal serum relative to the concentration, M, of that protein in the maternal serum, or F/M, was taken as a measure of net maternofoetal transfer. The results are shown in Table 1. It must be emphasized that the F/M ratios in Table 1 represent the relative transfer efficiencies for the different proteins, or the relative protein clearances of maternal serum resulting from maternofoetal transfer, in these experimental conditions; that is, tracer amounts of labelled protein in the presence of normal maternal serum concentrations of the homologous γG globulin.

It will be noted that guinea-pig γG traversed the maternofoetal barrier in each of the three species more readily than did any of the other γG globulins, and that the efficiency of maternofoetal transfer in each species was least for human serum albumin. In decreasing order, the efficiency of maternofoetal transfer of γG globulin in

the mouse was guinea-pig \geq human > rat > bovine = mouse; in the rat, the order was guinea-pig > human = mouse > rat \geq bovine. In the guinea-pig, the order for those γG globulins studied was similar to that in the mouse and rat, that is, guinea-pig > human > mouse, but the maternofoetal transfer of these immunoglobulins in the guinea-pig was less than that for any γG globulin in the mouse and rat; the maternofoetal transfer of γG globulin in the guinea-pig was comparable with that of human albumin in the mouse and rat, the least efficiently transferred protein in the latter species. Thus, although selectivity in protein transfer was noted in each of these species, such transfer was far less efficient in the guinea-pig than in the mouse and rat.

The average half lives of guinea-pig γG , human γG , mouse γG , bovine γG and human albumin in the mouse are, respectively: 4.93, 4.53, 4.03, 1.610 and 0.7511 days. Although the species orders for half life and maternofoetal transfer for these proteins are similar, the data do not give much support to a possible relation between the two processes in the mouse. The differences in maternofoetal transfer of guinea-pig γG , human γG and mouse γG in the mouse are much greater than the relatively small differences in the average half lives of these proteins. In addition, labelled mouse YG and bovine YG have similar maternofoetal transfer rates in the mouse but quite different half lives. Nor can the differences in maternofoetal transfer that appeared between species be explained in terms of differences in half lives: the F/M ratio for guinea-pig γG and human γG in the mouse averaged fifty times the ratios for the same proteins in the guinea-pig, whereas the half lives of these proteins in the mouse, 4.9 and 4.5 days, respectively, were virtually the same as in the guinea-pig, 4.2 and 3.8 days, respectively. Of course, a possible similarity in underlying mechanisms of the two processes is not precluded by these data, but it is apparent that there are specific kinetic differences between plasma protein catabolism and maternofoetal transfer.

The half lives of these proteins and the maternofoetal transfer efficiencies were determined in similar conditions, that is, with tracer amounts of labelled protein in the presence of normal concentrations of homologous protein, and so comparison between these half lives and the F/M ratios is valid. Nevertheless, it should be noted that the F/M ratio for human γG , at least, is dependent on concentration, and thus the F/M ratios may not remain the same at higher maternal concentrations of the heterologous γG globulin or at lower concentrations of the homologous γG globulin (our unpublished work). At a maternal serum concentration of human γG in the mouse comparable with that for mouse γG , approximately 1,000 mg per cent, the F/M ratio for human γG is less than a fifth that for mouse γG ; thus, at this concentration, the rate of transfer of human γG is less than that of mouse γG .

The high F/M ratios for human and guinea-pig γG in the mouse compared with those for mouse γG indicate that mouse γG at normal maternal serum concentrations competes little, if at all, in the transport system for human or

guinea-pig YG. It is therefore interesting that the mouse

Table 1. Serum concentration of labelled protein in foetus relative to that in mother 24 h after injection into mother

has a maternofoetal transport system which is relatively specific and more efficient for human and guinea-pig YG globulins than for its own immunoglobulin, although the mouse presumably never came into contact with these molecules before.

This investigation was supported by grants from the US Public Health Service.

Transference of Maternal Passive Immunity to Vaccinia Virus in Mice

ADULT mice are highly resistant to experimental vaccinial infection, but suckling mice succumb to relatively low doses of virus introduced into the inter-scapular fat pad1. Transfer of protective antibody from immunized dams to their offspring has been described in this species for the viruses of variola2, herpes3, foot and mouth disease4 and Friend leukaemia⁵. In this communication, I report the transfer of antivaccinial immunity from actively immunized pregnant mice to their young. The Porton strain of albino mice and the WR strain of vaccinia virus were used throughout. The biological characteristics and method of assay of WR vaccinia virus are recorded by Turner⁶. A single batch of virus (titre 2×10^7 plaque forming units (P.F.U.)/ml.) was used, collected from chick embryo fibroblasts and stored in small volumes at -70° C.

The first experiment was designed to determine how late in pregnancy mice could be treated with virus so as to give birth to pups resistant to challenge with live virus. Breeding pairs of mice were kept in separate cages. At different times after mating, pregnant mice were inoculated intraperitoneally with a single dose of 0.1 ml. of virus

Table 1. TRANSFER OF PROTECTION TO LITTERS FROM MICE IMMUNIZED DURING PREGNANCY

Interval between vaccination of pregnant mouse and	No. of litters	Total progeny dead
parturition (days)	challenged	Total challenged

suspension containing 105-106 P.F.U. (Table 1). The male mice were removed on about the tenth day of pregnancy. The baby mice were challenged within 24 h of birth by an injection into the fat pad of 0.05 ml. of virus suspension containing 10^4 P.F.U. (equivalent to $100 LD_{50}$). Deaths were recorded daily for 3 weeks. Control litters from unvaccinated mothers were similarly challenged; the mortality was 100 per cent. Female mice vaccinated between 8 and 18 days before parturition synthesized and transferred protective amounts of maternal antibody to almost all their foetuses. The decrease in protection with intervals of 20-22 days is presumably a result of the decline in the concentration of circulating antibody. This single injection conferred protection on three to four subsequent litters; but the mothers may have been re-immunized by contact with the live virus used for challenge of the litters.

These vaccinated mice were used to assess the role of the prenatal and mammary routes of antibody transfer in a cross-fostering experiment. At the same time, a second group of virgin females was mated, one breeding pair to a cage. The pregnant mice were inspected frequently and within 8 h after parturition litters were exchanged between the two groups. Litters which remained with their mothers for longer than this time were treated as controls. All progeny were challenged at the time of exchange. Deaths were recorded daily for 21 days. The difference in the degree of protection between the two cross-fostered groups was very significant ($\chi^2 = 15.7$ with l d.f.; P < 0.001; Table 2). The distribution of daily mortality in the two groups was also different (Fig. 1) The difference between the mean times to death, 5.5 days for group A and 7.8 days for group B, was highly significant (t=19 with 95 d.f.; P < 0.001).

Table 2. Transfer of protective antibody by the uterine ani-mammary routes

	Route of passive immunity	Status of mothers	Status of foster- mothers		surviving/No. of
В	Mammary	Unvaccinated	Vaccinated	10	8/66
	Uterine	Vaccinated	Unvaccinated	9	28/66
	Both	Vaccinated	None	2	14/15
	Neither	Unvaccinated	None	3	0/16

Other workers have challenged the mice at 3 days2. 5 days4 or 14 days3 after birth, by which time the suckling mouse has absorbed a considerable amount of antibody through the intestine. By challenging the litters within 8 h of birth the protective effect of the antibody secreted in the milk was negligible ($\chi^2 = 2.2$ with 1 d.f.; P > 0.05. Table 2). Thus, although it is not possible to compare the relative maximum efficiencies of the pre- and postnatal routes of transfer of antibody, the results of these experiments indicate that there is a substantial prenatal absorption of antibody by the foetal mouse, greater than has hitherto been suspected?. Kempes found that the titres of haemagglutinin-inhibiting antibody of cord blood of newborn human infants were significantly higher than those of their mothers who had been immunized with smallpox vaccine. It would be interesting to determine

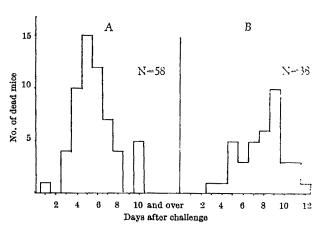

Fig. 1. Histograms of the daily mortalities in two groups of cross-fostered litters. A, Progeny of unvaccinated mothers fostered by immunized mothers. B, Progeny of immunized mothers fostered by unvaccinated mothers.

whether a similar mechanism for antibody concentration exists in the pregnant mouse.

PHYSIOLOGY

Coelomic Water Volume Control in the Antarctic Sea-star Odontaster validus

ASTEROIDS are usually considered to have little or no control over the volume of water in the perivisceral coelom, the body wall being freely permeable to water and most ions¹. The Antarctic asteroid *Odontaster validus* Koehler, however, apparently regulates coelomic water volume to the extent of maintaining seasonal fluctuations2. This species is a "cushion" type asteroid with small, loosely scattered ossicles in a thin body wall permitting considerable flexibility in body shape. Individuals often markedly swollen with coelomic water were collected, while others were "normal" or even shrivelled. Many animals lost weight during successive weighings, and in some cases the decrease was more than 40 per cent of the original wet weight. Other animals maintained their original weight, or gained up to 30 per cent of their original wet weight, during successive weighings. Animals in the field had significantly less coelomic water in March and April, and significantly more in June, than at other times during the year. This seasonal fluctuation did not correlate with fluctuations in gonadal, pyloric caecal or intestinal caecal size. Several experiments, carried out at McMurdo Station, Antarctica, and showing other possible aspects of coelomic water volume regulation in O. validus,

are described here.

Two series of weighings, using three animals each, were followed with the animals placed first in sea water diluted 50 per cent with distilled water, and then returned to full strength sea water (Fig. 1). Wet weight rose slowly in one animal after it was placed in the 50 per cent sea water solution, while in the others wet weight fluctuated with little real change. The lack of expected marked increase in weight as a result of water uptake1 could be caused by holes broken through the body wall allowing water to escape, as occurred in similar experiments with Asterias rubens3. The animals recovered, however, and became active when returned to full strength sea water, and they all lost weight. The loss of weight probably resulted from the coelomic fluid becoming hypo-osmotic to sea water while in the 50 per cent sea water solution, and indicates either that the body wall remained intact or that the possible holes were quickly sealed.

When collected, most specimens of O. validus were turgid as if water in the perivisceral coelom was held at a slightly positive pressure. After being "relaxed" for 18-24 h in a solution of 1 part isosmotic magnesium chloride to 1 part full strength sea water, most specimens lost water (Fig. 2A), became flaccid and sluggish, and reached a constant weight, that is, they seemed to have lost their ability to hold coelomic water under pressure. When replaced in sea water after the treatment with isosmotic magnesium chloride, most animals regained activity and

returned to their original weight within 20 h, and some even gained much over their original weight (Fig. 2B). Binyon⁴ found a similar drop in weight in A. rubens in isosmotic glucose and choline chloride solutions because of salt and water loss as a result of the impermeability of the glucose molecules and choline ions to the body wall. But he also showed that magnesium ions in the perivisceral fluid remained isoionic to the outside medium. The effect of magnesium ions on O. validus is therefore probably caused by something other than their being impermeable to the body wall.

The loss of the ability to control water volume in isosmotic magnesium chloride solution is further demonstrated by the fact that the wet weight of animals treated with magnesium chloride showed an almost linear relation to dry weight, whereas the original wet weight to dry weight relationship was very irregular because of variable coelomic water content in the different animals The smallest animals, however, did not lose weight in the magnesium chloride solution, and some even gained weight. These very small animals are the ones shown to have gained weight in Fig. 2A.

A final series of weighings, shown in Fig. 4, illustrated another aspect of control of coelomic water volume in

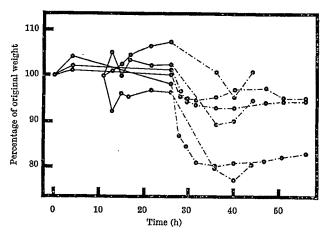

Fig. 1. Wet weight changes in six specimens of O. validus in 50 per cent sea water (——) and after their return to full strength sea water (——). Initial wet weights ranged from 4.0 to 10.8 g.

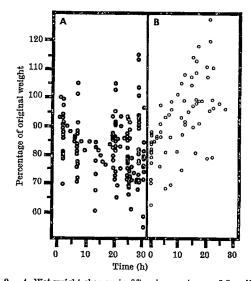

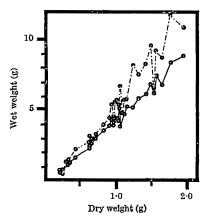

Fig. 2. A, Wet weight changes in fifty-nine specimens of O. validus in isosmotic magnesium chloride solutions. Different series of weighings, varying in exposure and weighing times, are shown. Two animals, both weighing 0.7 g, gained weight as did a third weighing 3.3 g. All the other animals, ranging in initial weight from 1.5 to 35.4 g, lost weight. B, Wet weight changes in twelve specimens of O. validus when returned to sea water after 18-24 h exposures to isosmotic magnesium chloride solutions. Initial wet weight ranged from 4.0 to 14.3 g.

O. validus. The weights of three animals, maintained in sea water at -1.5° C and fed on beef and seal meat every 3 to 5 days, were followed for 1-2 months. The smallest animal followed a striking periodicity in wet weight with a period of 10 days. The other small animal had a periodicity in wet weight of 15-20 days, while a suggestion of a periodicity of about 60 days occurred in the large animal. These periodicities did not correlate with the feeding or water changing regimes, nor with any other recognized fluctuation.

Gemmill⁵ found weight increase in the asteroid Porania pulvillus during flagellary-mucoid feeding activity. validus is also a flagellary-mucoid feeder2, and the turgidity found, and its fluctuations, may be a consequence of such feeding activity. From evidence of pyloric caecal growth, however, feeding was most intense during the late summer when the coelomic water volume was lowest2.

Another possible means of controlling volume is by the regulation of small osmotically active organic molecules. Such molecules are important for the control of coelomic water volume in some sipunculids, and the control of at least intracellular volume in asteroids, and echinoids.

Relation to dry weight to initial wet weight (----) and to wet after 18-24 h exposures to isosmotic magnesium chloride solutions (-----) in twenty-nine specimens of O. validus.

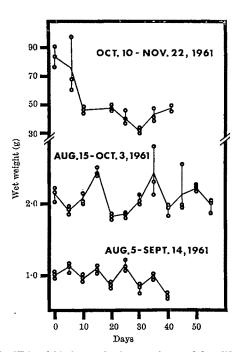

Fig. 4. Wet weight changes in three specimens of O. validus maintained in the laboratory. Each dot represents one weighing, and three weighings were made 1 h apart every 5 days.

Being common in very shallow Antarctic waters2, specimens of O. validus are exposed occasionally to summer fresh water run-off from the surrounding lands. ability to control body volume and withstand hypo-osmotic conditions may be particularly important at these times.

Haemostatic Plugs in Experimental Scurvy

Born and Payling Wright¹ found that the blood platelets of weanling guinea-pigs fed on a scorbutogenic diet show decreased adhesiveness. These results suggested to them that the haemorrhages of scurvy might be caused either by the failure of the platelets to adhere to form effective haemostatic plugs, or because of some unexplained mechanism, to maintain normal capillary resistance. We have repeated these experiments and, in addition to measuring the adhesiveness of platelets to glass, we have studied the formation of haemostatic plugs by direct observation.

Weanling guinea-pigs, Hartley-Dunkin albino strain, weighing 167-220 g, were divided into two groups; one was fed a standard diet, the other received a scorbutogenic diet2 supplemented with autoclaved reconstituted milk and green vegetables. Control animals gained weight, while those on the scorbutogenic diet were almost at their initial body weight when clinical signs of scurvy appeared. The animals were anaesthetized with intraperitoneal urethane. A loop of intestine with its mesenteric vessels was withdrawn through a small incision in the abdominal wall, and the arteries were observed and major injuries inflicted as described by Honour and Ross Russell3. Several arteries were subjected to such injuries in each animal. Blood was withdrawn from the abdominal vena cava and mixed with one part in ten of 3.8 per cent trisodium citrate. Platelet adhesiveness was measured by a modified rotating bulb technique4; platelet counts were made using the method of Brecher and Cronkite before and after rotation of the blood for 40 min. Packed red cell volumes were measured by the haematocrit method. The animals were divided into two groups of six. One group was maintained on the scorbutogenic diet, the other on a standard diet. All animals on the scorbutogenic diet showed loss of hair, had haemorrhages and were in such poor condition by the fourth week that three were lost through anaesthesia during preparation. In the remaining three, several mesenteric arteries in each animal were subjected to major injuries which resulted in profuse bleeding, but at all sites a firm haemostatic plug formed and the bleeding ceased. White bodies

developed at all injury sites within the lumen of the vessel. Of the control group, two died as a result of anaesthesia. In each of the remainder several mesenteric arteries were injured and at each injury site firm haemostatic plugs and intraluminal white bodies formed. There were no detectable differences in the formation of haemostatic plugs and white bodies between the two groups of animals. Platelet adhesiveness was measured in too few animals for any great weight to be attached to the results, but the scorbutic animals showed lower adhesiveness than the controls (27 per cent compared with 36 per cent). There was a small difference in packed red cell volumes (scorbutogenic animals, 36; controls, 38).

These observations agree with those of Born and Payling Wright in the matter of platelet stickiness, but they also show that, despite the presence of a defect in the blood platelets, the haemostatic plugs produced by injury are firm and have their integrity unimpaired. It would thus seem that the haemorrhages of scurvy are not attributable to failure of haemostatic plugs to form, and the maintenance of a normal capillary resistance as suggested by Born and Payling Wright may still be implicated.

Vascular Organization of the Human Placenta

The currently accepted theory of maternal blood flow through the intervillous space of the primate placenta1 is that maternal blood entering through basally situated spiral arterioles spurts up towards the chorionic plate under the influence of the vis a tergo of the maternal arterial pressure, spreads laterally and falls back to drain through basal venous openings. Short circuiting from artery to adjacent vein is believed to be avoided purely by virtue of the arterial pressure. This theory based on cineangiographic evidence takes no account of the structure of the foetal portion of the placenta. The latter consists of numerous lobules or cotyledons of which the principal fifty to sixty are arranged in the form of hollow centred bush-like structures as seen in corrosion casts of the foetal vasculature^{2,3}. Each lobule arises by a main chorionic stem, and is supplied through a major branch of an umbilical artery. Subsequent branches supply an extensive capillary network within the mass of terminal villi which crowd round the central intralobular space. This lobular pattern can be recognized in histological sections in the form of dense masses of villi orientated round cavities. Interlobular and subchorial areas show greater separation between the villi.

It has been suggested, on theoretical grounds, that the hollow centres of the lobules are the site of entry of the maternal blood into the intervillous space3,5,6 with some recent experimental confirmation derived from eineangiography7,8, but this has been denied for the human placenta by evidence based on placental reconstructions.

The work reported here indicates that the anatomical relationships of the maternal and foetal circulations can be determined in the delivered human placenta by the use of simple techniques and that the pattern displayed throws light on the nature of the circulation through the intervillous space.

If the maternal surface of a freshly delivered placenta is examined under a good light the thin-walled spiral arteri-

oles can be defined by squeezing the placenta gently so as to fill them in retrograde fashion from the intervillous space. It is then possible to inject a number of the vessels with barium gelatine solution ('Micropaque', Damancy and Co., Ltd., with 3 per cent gelatine), through a fine nylon intravenous cannula (size 2-3, French) so that any desired quantity of contrast enters the intervillous space. injection mass is adjusted to a viscosity of about twice that of blood by addition of the "neutral medium" of Damancy and Co. The injected vessels are surprisingly large with a diameter of 2-3 mm (Fig. 1). Separate injection can be made into the placental veins and into the foetal vessels of the umbilical cord. The placenta is then fixed in 10 per cent formal saline before further

study by radiology, dissection and microscopy.

Examination of injected specimens shows that the spiral arterioles can enter the intervillous space either over the centre or at the periphery of the foetal lobules. On dissection it is apparent that the injection mass invariably collects in the loose centre of the lobule irrespective of its site of entry. Injection through the decidual veins selectively fills the subchorial lake and interlobular spaces with little tendency to percolate to the centre of the lobules. X-ray studies confirm the orientation of the

Fig. 1. Portion of fixed placenta viewed from maternal surface showing several injected spiral arterioles.

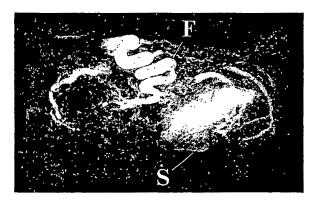

Fig. 2. Lateral X-ray of portion of fixed placenta. Contrast has entered intervillous space through spiral arteriole (8) and is surrounded in basket fashion by branches of foetal artery (F). Note an unfilled intralobular space on the left. ...

foetal placental vascular tree round the sites of spiral arteriolar inflow (Fig. 2). Histological sections show that the injection mass is surrounded by the densely packed masses of villi of the lobular shell which separate it from the loose interlobular zones (Fig. 3).

This investigation supports the hypothesis that maternal blood enters the centre of the foetal lobules although it is not yet possible to state whether each lobule is always supplied by a single spiral arteriole. The vascular pattern has important implications. Because the spiral arterioles of the decidua develop from those of the endometrium it follows that to achieve the structural relationship observed near term, the foetal lobules must have developed round the arteriolar entries. This has several predictable results. First, most of the terminal villi come into contact with the richly oxygenated maternal blood as it enters the intervillous space. Second, the dense masses of villi are likely to form sufficient resistance to flow to allow a substantial arterial pressure to be achieved in the intralobular space as envisaged by Reynolds. Third, the terminal villi act as baffles which result in uniform lateral dispersion of blood flow throughout the lobule. Finally, as growth of the placenta proceeds, loose spaces are left between the lobules and will form natural pathways for venous drainage. The circulation through the intervillous space may be envisaged as in Fig. 4.

All conditions essential for development of a logical maternal placental circulation and for achievement of

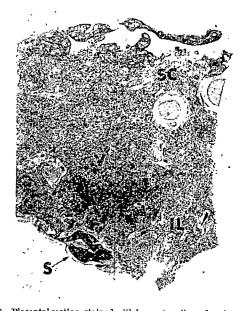

Fig. 3. Placental section, stained with haematoxylin and eosin, \times c. 3.5. Contrast has entered placents through spiral artery (S) and collected in the intralobular space where it is separated from interlobular space (IL) and subchorial space (SC) by dense masses of villi (V).

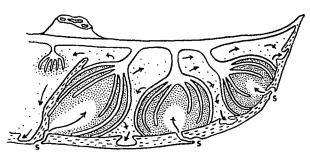

Fig. 4. Circulation through intervillous space. Diagram indicates main chorionic stems with spiral arterioles (S) discharging into the centre of the lobules. Density of stippling indicates density of villi and arrows show directions of flow through intervillous space.

optimal conditions for placental transfer may well be fulfilled purely by preferential growth of the foetal lobules round the entries of maternal spiral arterioles into the intervillous space. The central role of the spiral arteriolar entries in the organization of the intervillous circulation receives further support from a recent study of aortograms performed on pregnant women.

Current arguments about the existence of an intervillous capillary space¹⁰ may perhaps be resolved on the basis of this pattern. If the areas filled readily by high viscosity injection media in the delivered placenta accord with conditions in the uterus, then the intralobular, interlobular and subchorial spaces are all of greater than capillary dimensions, whereas the crowded masses of terminal villi making up the shell of the lobule may well form a functional intervillous capillary space.

I wish to thank Professor J. P. M. Tizard for advice

and encouragement, and Dr G. S. Dawes for much helpful discussion.

Static Method for determining **Blood Yield Stress**

THE yield stress or shear strength of a suspension is the critical stress which must be applied before the suspension will flow. This property of blood has been determined in the past by the extrapolation to zero shear rate from viscometry at higher shear rates, for example, (a) the extrapolation of low shear rate Couette viscometric data1-3, (b) the extrapolation of capillary tube viscometric data and (c) the torque-decay curve of the Couette viscometer2,3

These methods for determining yield stress have been open to question. Some workers have noted that blood does not seem to have a yield stress if sufficiently low shear rates are achieved. On the other hand, if torque decay is measured, a yield stress may be detected. It has been suggested that this discrepancy may be caused by the development of a marginal plasma layer at low shear Thus a method based on a different principle is needed. A settling technique for determining yield stress has been suggested before. This approach has been developed to provide a method for determining blood yield stress that is independent of blood viscometry.

A glass capillary tube of inside diameter about 0-20 cm was drawn to a fine taper of about 30µ inside diameter, and the tip was broken to allow the tube to be filled with liquid. The tapered tube was then filled with blood, sealed at the bottom, for example, with clay, and allowed to stand in a vertical position for about 5-10 min (Fig. 1). In this time, settling of cells may be observed. There will, however, be a diameter for the inside of the tube above which no settling occurs. This

is known as the yield diameter, D_y . No settling occurs above the yield diameter because the weight of the red cell network is capable of being supported along its lateral surface. It is essential to note the first break in structure and to avoid trapping bubbles in the blood which disrupt the suspension structure. If allowed to stand too long, the cell suspension structure may slip and cause secondary breaks.

From a consideration of the force balance involved, it is possible to calculate the yield stress from the yield diameter. At equilibrium the force acting along the lateral surface just equals the weight of the cells supported. This is expressed by

$$\tau_{y} = \frac{(g)(\varphi)(\rho_{c} - \rho_{p})D_{y}}{4\cos\theta} \tag{1}$$

where ρ_p is plasma density; ρ_c is cell density: D_y is yield diameter; τ_y is yield stress; g is the gravitational constant; φ is the volume fraction of red cells, and θ is the angle of taper, which is very small in the drawn capillary tubes, so that $\cos\theta \cong 1$.

The density difference between plasma and cells was determined by the copper sulphate method by noting the solution densities which just suspend plasma and centrifuged cells. This density can be measured to 0.001 g/ml. by this method. The density difference $(\rho_c - \rho_p)$ does not change substantially for a relatively large range of temperatures, and remains nearly constant for many samples measured. The density difference error is within 4 per cent.

4 per cent.

The yield diameter was measured using a low power microscope with a graded eyepiece. A drop of immersion oil on the glass tube aids the measurement. At least three replicates were measured and the error was within 5 per cent. The blood yield stress is then calculated from equation (1).

The values obtained by this method were compared with those for yield stress obtained by extrapolation of a plot of (shear rate) against (shear stress) from shear rates of between 1 and 1,500 sec⁻¹ (Fig. 2). Brookfield cone and plate viscometers covering this shear rate range were used. The viscometers were calibrated with NBS oil and checked with Brookfield standard oil. The blood samples were drawn either from healthy donors or from

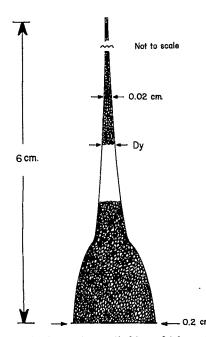

Fig. 1. The yield diameter in a vertical tapered tube containing a red cell suspension.

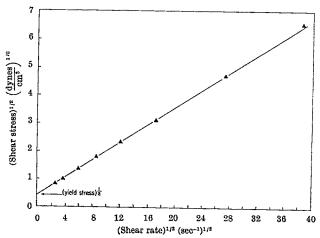

Fig. 2. A typical plot of cone and plate viscometry for determination of yield stress.

patients under anaesthesia, undergoing surgery. The blood from healthy donors was drawn in ACD buffer while that from surgical patients was placed in heparin as anticoagulant. Dilutions of cells were made by suspending centrifuged packed cells in an appropriate volume of plasma obtained from the same blood.

In Table 1, the static yield stress of various samples of blood with varying haematocrit and at different temperatures is compared with the yield stress derived from viscometry determined by a Brookfield cone and plate viscometer.

The results indicate good agreement between the yield stress determined by the static method and yield stress determined by extrapolation in sixteen of nineteen experiments (Fig. 3). The density difference ($\rho_c - \rho_p$) is nearly constant at 0.061 g/cm³.

The agreement between the static method and the extrapolation of shear rate information from above 1 sec⁻¹ suggests that Casson's equation applies below 1 sec⁻¹ as well as above 1 sec⁻¹ for blood.

The yield stress is a measure of the aggregation function of cells and may be of critical importance in determining flow in response to small stresses. This method makes possible easy determination of this property of blood in health and disease.

The values in the literature for blood yield stress determined in a GDM Couette viscometer seem to be about five times less than those determined with a cone and plate viscometer^{4,7}. Yield stress determined by the static method described here, however, agrees with the yield

Teratogenic Effect of Cadmium and its Inhibition by Zinc

DURING a study of the teratogenic effects of heavy metals on mammalian embryos, we have been able to produce severe developmental malformations in golden hamster embryos by the intravenous injection of 2 mg/kg of cadmium sulphate into pregnant mothers on the eighth day of gestation. These malformations consisted of a specific effect on the face and upper jaw, ranging from a simple mid-line cleft to almost complete obliteration of normal facial architecture. A few other malformations apparently also induced by cadmium in this dose were occasionally found. These consisted of anophthalmia, digital and other limb defects, rib fusions and exencephaly. The simultaneous administration of 2 mg/kg zinc sulphate almost completely inhibited this marked teratogenic effect of cadmium. The particular susceptibility of the germinal epithelium of the testis and the rodent placenta to the toxic effects of cadmium has been described1.2. This toxic effect of cadmium has been attributed to alterations in the endothelium of the vascular beds in these affected organs2,3.

Timed matings of female hamsters were obtained by a manner previously described4. On the eighth day of gestation, the animals were injected intravenously with

either 2 mg/kg of cadmium sulphate, 2 mg/kg of zinc sulphate or a mixture of 2 mg/kg of cadmium sulphate plus 2 mg/kg of zinc sulphate made up in distilled water. The volume of the injected solutions was standardized at 1.0 ml./100 g of body weight. On the tenth, eleventh or twelfth day of gestation the embryos were collected and examined for gross external malformations. At this time, the number of resorption sites was also ascertained.

Table 1 shows that zinc alone provoked a very mild teratogenic response. In identical conditions, the intravenous injection of cadmium caused a marked embryocidal and teratogenic effect; approximately 66 per cent of the embryos showed developmental malformations. The most striking malformation was a facial abnormality affecting the upper jaw and resulting in varying degrees of facial When zinc was combined with cadmium at the time of injection, however, the teratogenic and embryocidal effects of cadmium were markedly reduced. The maternal animals survived the injections well and no pathological changes were noted when they were killed.

L. EFFECT OF CADMIUM, ZINC AND CADMIUM-ZINC ON EMBRYONIC MORTALITY AND MALFORMATIONS IN THE GOLDEN HAMSTER

	No. of mothers treated	No. of embryos recovered	No. of embryos resorbed	No. of embryos malformed
Controls (distilled water)	10	116	7	1
Cadmium (2 mg/kg)	20	204	44	131
Zine (2·0-6·0 mg/kg)	12	142	4	2
Cadmium-zine (2 mg/kg of each)	10	120	6	5

The protective effect of zinc could be related to a critical physiological cadmium: zinc ratio which has been demonstrated in a variety of ways. Schroeder has shown that high renal ratios of cadmium: zinc have been associated with arterial hypertension in rats and that this hypertension can be reversed by a zinc chelate. Administration of zinc to animals loaded with cadmium will also prevent the testicular lesions previously described6

Recent studies of the teratogenic effect of lead ions have emphasized the marked teratogenic effect of lead on the tail bud of hamster embryos7. The specificity of the teratogenic effect of cadmium on embryonic facial architecture points to another specific organogenetic effect of a heavy metal teratogen. It is tempting to hypothesize a localized specific effect on some metalloenzyme which competes for both cadmium and zinc. These experimental results point the way to further research concerning the specificity of the teratogenic effects of heavy metals.

Cerebral Potentials evoked by Pattern Reversal and their Suppression in Visual Rivalry

SINCE the introduction of techniques to improve the signal to noise ratio1, the number of publications on human visual evoked potentials has been considerable; usually the stimulus has been a brief flash or series of flashes (flicker) on an unstructured field, but recently the interest of patterned fields has become apparent²⁻⁴. Following a suggestion by Gross et al.⁵ we have demonstrated the effectiveness of "pattern reversal", without change in the total luminous flux, in evoking visual cortical responses and have applied the method to the investigation of binocular rivalry.

As in our previous experiments on binocular rivalry, the target area was limited by a hole 3.75° (2.5 cm at 37 cm distant) in diameter, or less, in a black surround, usually viewed by one eye. The target was a thin transparent 'Cellophane' sheet with a regular pattern of black horizontal bars printed on it, lying immediately behind the hole and moved vertically up and down by a linear transducer. It was transilluminated by a tungsten filament lamp behind a diffusing screen of white paper; the luminance of the clear parts of the target was 200 ft.-lumens or less. For rivalry experiments the second eye viewed a congruent target, similar in all respects except that its parallel black bars were vertical; it could be stationary or moved from side to side by a second transducer.

The electroencephalogram was recorded from an electrode on the midline 3 cm above the inion, with reference to an electrode at the vertex or on one ear lobe; in the former case an ear-vertex derivation was used to check the absence of response from the vertex lead. After amplification the responses were averaged by a Biomac 500 averaging computer, usually 128 sweeps of 500 msec duration. The averaged responses were stored in digital form on punch tape and written out by an X-Y plotter.

The target used most often had fifty-eight alternating black and white bars of equal width and was 2.5 cm in diameter; the transducer was adjusted to move the target by one bar width, a distance of 0.43 mm or 4' of visual angle, so that the black-white pattern was wholly reversed; the rise or fall time was 3 msec (10-90 per cent amplitude). In these conditions good evoked responses were obtained in all the twelve subjects examined for frequencies in the range from 2 to 20 c/s (Figs. 1 and 2). It should be noted that the frequency of movement was 1-10 c/s; upward and downward displacements of the transducer gave similar responses so that the response frequency was twice the transducer frequency. Exactly similar responses were obtained when the bars were placed vertically and moved horizontally (Fig. 1, channel The maximum amplitude of response was about 12 μV peak to peak, obtained at 12 c/s.

Three sizes of target (25, 12 and 6 mm in diameter) have been used and the same trends are clear in all subjects although the effect of target size has so far only been studied systematically in one. When the visual angle of the target was increased from 56' to 1° 52' the response amplitude rose by 55-75 per cent, depending on frequency; a further increase to 3° 45′, however, caused only a 16 per cent increase in amplitude, or less, except at the highest frequency (20 c/s) at which the responses with the smaller targets had been ill defined. In this and other subjects, looking at the edge of the target caused marked decrease in response amplitude; it fell almost to zero when the fixation point was a few degrees to either Thus the response, like those to flash stimulation, must be largely the result of foveal stimulation and probably requires good resolution of the pattern; this is further suggested by the sharp decrease in amplitude when the target is thrown out of focus by a suitable lens.

With the largest target, a ten-fold reduction of the luminous flux caused little reduction in the amplitude of the response. Some other target materials have been used and a chequer pattern (one black-white pair = 27') seemed particularly effective (Fig. 2). The response to two-eyed stimulation was larger and could be nearly twice the voltage of that to a unilateral stimulus.

Two types of control have been made. The theoretically more satisfactory is to set the transducer to move the target by a black—white pair width so that there is no apparent movement. In these conditions, the responses were greatly reduced although a small component at the stimulus frequency might remain, possibly caused by target overshoot, resulting in some visual stimulation. An alternative control was to cover the target with a sheet of plain white paper; when the movement of the target was through one bar width no response was recorded at the stimulus frequency.

The term binocular rivalry implies that when different images fall on congruent areas of the two retinae the subject usually perceives first one image, then the other; one eye is said to be dominant while the other is said to be suppressed. It has been reported. It has been reported. It has been reported evoked responses than when it is applied to the suppressed eye. In our experiments we used the same target material as that described except that the patterns of horizontal or vertical bars were stationary and transilluminated by gas-discharge flashes or 100 per cent square wave modulation of a fluorescent source. We found no consistent differences in amplitude between responses to stimulation of the

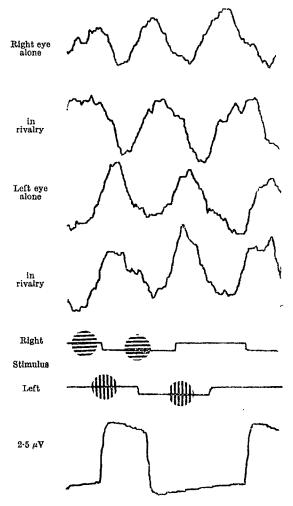

Fig. 1. Pattern reversal in visual rivalry. Each trace is the average of 128 sweeps and lasts 250 msec; response frequency, 12 c/s. The targets, 6 mm in diameter (56'), have alternating black and white bars 0.43 mm wide; for the right eye they are horizontal and move vertically by one bar width; for the left eye they are vertical and move laterally. The two traces above the calibration signal, if viewed at 37 cm, show the actual size of, and change in, the targets and the temporal sequence of their movements, which are arranged so that the responses from stimulating the eyes separately are 180° out of phase (channel 1 = right eye, channel 3 = left eye). When the eyes are stimulated together rivarity occurs and the subject sorts the responses by pressing either of two switches, according to whether the right eye (channel 2) or left eye (channel 4) is dominant. It will be seen that the responses during rivalry are as large as or larger than during single-eyed viewing, which suggests that the non-dominant eye has not contributed to the trace.

dominant or suppressed eyes, confirming the negative results of Kaufman et al.10.

Using pattern reversal as the stimulus, we have so far investigated seven subjects, two of whom found it impossible to sort dominance and suppression reliably. In one type of experiment only one of the targets moved and the subject indicated by two switches which eye was dominant, causing the responses to be stored in the corresponding channel of the Biomac⁶. Thus the amplitudes of the two stored signals represented the mean amplitudes of the responses to stimulation of the one eye when it was dominant or when it was suppressed. In twenty-four experiments of this kind on five subjects (2, 2, 5, 10 and 5) a clear reduction in amplitude, easily seen without measurement, was present in twenty-two cases; one subject gave two doubtful results out of ten; in no case was the opposite effect seen. No such consistent effects were found with conventional flicker.

In a second type of experiment, stimuli were presented 180° out of phase to the two eyes (Fig. 1); the subject sorted the responses as described. If suppression were complete and if this sorting were perfect it would be expected that the two traces would be similar to those obtained for stimulation of either eye alone, whereas without suppression or without sorting each channel would contain an equal mixture of the out-of-phase responses and both traces would approximate to straight lines. This was the result when using conventional flicker, whereas with pattern reversal the four subjects investigated (twenty experiments: 1, 8, 4 and 7) gave clearly positive results apart from three out of seven in one subject which were equivocal. Two of the subjects gave out of phase responses as large as or larger than those

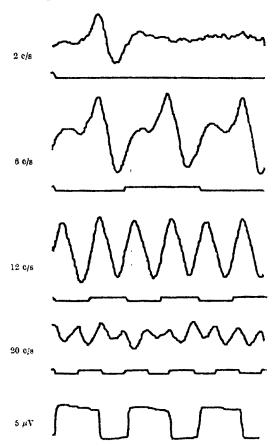

Fig. 2. Responses in one subject to stimulation of the right eye by vertical movement of a chequer pattern through one square, or 13.5'. Field diameter, 12 mm or 1° 52'. Each trace is the average of 128 responses and lasts 500 msec. Channel 1 is the response to downward movement of the pattern, indicated by the trace immediately below it; the remaining channels show the similarity of responses to up or down movements at various frequencies. Note that the transducer frequency is half the response frequency, the latter being given in the figure.

obtained when the eyes were stimulated separately (Fig. 1). Sorting cannot be perfect because of indecision and reaction time delays, so this is a surprising result which, if confirmed, raises interesting possibilities regarding the interaction of these responses at the cortical level.

If, as seems likely, the amplitude of the visual evoked response is dependent, in the first instance, on the number of approximately synchronized post-synaptic potentials in a given area, the work of Hubel and Wiesel¹¹ should have given an indication that a large uniformly flashed or flickering field was unlikely to be the optimum stimulus; possibly it will be found that the greatest number of clearly resolvable contrast borders gives the highest probability of activating the largest number of cortical cells.

Spehlman² has shown that the addition of pattern to a previously uniform flashing field can modify the form of the evoked potentials, but the present work suggests that reversal of the pattern, although without any change in the overall luminance of the field, is a particularly effective stimulus. This observation goes some way to explain the occurrence of lambda waves, as potentials evoked by scanning patterned fields, which have always seemed disproportionately large in comparison with the potentials evoked by bright flashes in the same subjects.

The apparatus necessary for this work was in part provided by the National Hospital for Nervous Diseases and in part by the Medical Research Council.

Central Patterning of a Vocalization in Fowl

Brown¹ has described a region of the lateral tegmental gray in red-winged blackbirds where focal electrical stimulation regularly produces alarm calls with very low stimulus intensities. We have found that stimulation of the same structure in chickens (stereotoxic co-ordinates A 4, L 4.5, V 4; ref. 2) produces clucking, which is an alarm call in this species. We present here evidence that this clucking is patterned in the central nervous system and does not depend on phasic input for its timing. This behaviour is favourable for analysis because the response is easily obtained under deep anaesthesia, making possible surgical manipulations.

The importance of central, as opposed to peripheral. control of the organization and timing of behaviour in animals has been emphasized by Bullock3. The subject is interesting because of its broad implications for the control of behaviour, but well documented examples are

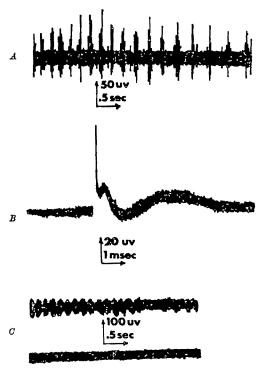

Fig. 1. Tracings of the response obtained while stimulating in the "calling" site and recording from: A, peripheral nerve T_4 ; B, ventromedial medulla, evoked response, and C, ventro-medial medulla—upper, bursting response and lower, no stimulation in "calling" site. Records A and C are from different birds with stimulating electrodes in similar but not the same sites.

still scarce, especially in vertebrates. Most of the experimental evidence for central control comes from studies of respiration or locomotion. Some examples which are often cited are rhythmic electrical discharges in the medulla of goldfish which match the frequency of respiration4, patterning of swimmeret movements in crayfish5, patterning of wing movements in flying locusts6 and fin movements in teleosts. The apparently centrally controlled locomotor rhythms in toads proved, on finer analysis, to be dependent on phasic sensory inputs.

The behaviour which we have studied, that is, clucking in chickens, resembles these examples in that it is quite regular and rhythmical, but it has additional interest as part of a highly evolved system of social communication. Our experimental procedure has been to implant electrodes in brain areas where stimulation produces clucking, then to stimulate these areas while recording electrical activity of motor nerves to the most important muscles involved in the production of the calls. Clucking is largely the result of brief contractions of the abdominal muscles, and spinal cord transections indicated that sections below T-4 had little or no effect while those at T-2 completely blocked it.

To determine the role of sensory feedback in the periodic activation of the abdominal muscles during clucking, nerve activity was recorded in nerves T_4 and T_3 while stimulating in the "calling" site (0.5 msec monophasic square wave pulses at 60 pulses/sec and 1.5-2.0 V). Recordings were made by impaling the nerve on electrodes made from double 0 insect pins, and the impulses were amplified by a Grass P_5 preamplifier and displayed on a cathode ray oscilloscope. Throughout the recording sessions the bird was anaesthetized with urethane (3 g given intravenously), and immobilized with tubocurarine chlorine (Abbott) (3 mg initially, 1.5 mg each 0.5 h as needed). The birds were artificially ventilated by passing warm moist air into the cannulated trachea and out through a hole in a thoracic air sac. In some cases, the curarine was allowed to wear off so that the rhythmic muscle movements reappeared and the movement artefact

on the cathode ray oscilloscope trace was used to confirm the phase relationship of the movement to the neural response. An example of the response in the nerve is illustrated in Fig. 1A. The rhythmic bursting in the absence of phasic proprioceptive or auditory input indicates that the stimulation in the brain elicits a rhythmic response which does not require peripheral feedback for its patterning.

The gross level of the central nervous system at which the patterning occurred was then examined. Analysis of degeneration from lesions in the calling site indicates that some fibres from the "cluck" site terminate both ipsi- and contra-laterally in the ventro-medial pons and medulla. This area was probed with semi-micro electrodes with a tip diameter of $10-20\mu$ insulated to within 0.15~mmof the tip. In two birds evoked responses were obtained (Fig. 1B) and in one of the birds bursts of activity could be detected at slow sweep speeds (Fig. 1C). No attempt was made to show directly that the response is in phase with the calling movements (again tubocurarine was used) but indirect evidence indicates that it is. The rate of bursting falls within the range of rates of calling usually obtained from the calling site (4-6/sec) and in this particular bird the site showed fairly rapid decay in calling and associated body movements in the noncurarized bird. The recorded response showed a similar decay (Fig. 1C).

These results indicate that the rhythmic body movements of the fowl which produce clucking calls in response to intracranial stimulation are centrally patterned and not dependent on phasic feedback for their timing. On the basis of our data we cannot evaluate the possible role of sensory input in modulations of the calls, but clearly the basic pattern is determined in the central nervous system.

Filling Gaps in the Vascular **Endothelium with Blood Platelets**

In thrombogenesis the interaction between platelets and the wall of the blood vessel is very important. It has been found that after a slight injury to the layer of endothelial cells, platelets adhere to the basement lamina which has been denuded of endothelial cells¹. Other platelets adhere to this first layer and form aggregates. Evidence from in vitro investigations has aided the elucidation of the mechanism of platelet-platelet interaction. This mechanism involves ADP, calcium, fibrinogen and possibly some other agents² in a biological chain reaction³. The mechanism of platelet—vessel wall interaction is not clear. It has been demonstrated in vivo and in vitro that platelets can adhere to collagen fibres4,5. Nevertheless, in experimental thrombosis where the layer of endothelial cells is the only visible site of injury, platelets adhere exclusively to the basement lamina. Collagen fibres are not involved in this process of adhesion1. It is not clear from these experiments, however,

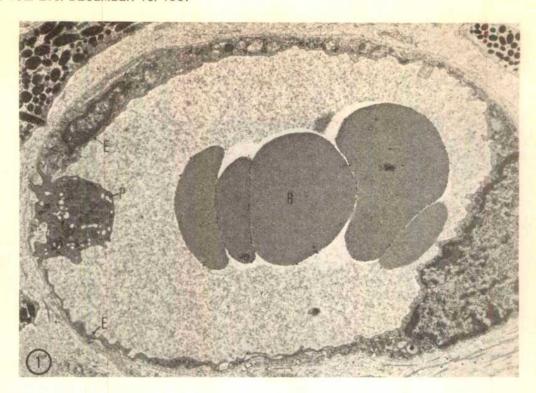

Fig. 1. Dilated capillaries from the iris of a cat. A platelet (P) fills a "gap" in the endothelial cell layer (E); R, erythrocyte (×8,000).

whether injury to the endothelial cells and the eventual release of tissue factors were necessary for the interaction of platelet with basement lamina.

Ultramorphological investigation of the cat iris showed that similar interaction between platelet and basement lamina can occur in capillaries which show no visible injury to the endothelial cell layer. We have therefore made a comparative study of capillaries from the iris of normal animals, of animals pre-treated with reserpine (2 mg/kg given intraperitoneally, 20 h before the experiment) and of other animals 1, 2 and 7 days after sympathetic denervation.

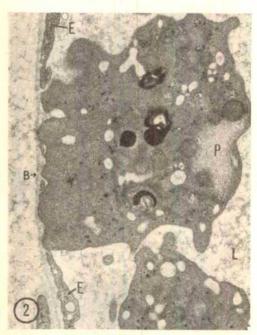

Fig. 2. Dilated capillaries from the iris of a cat. A platelet (P) in close contact with the basement lamina (B) in a "gap" between two endothelial cells (E); L, capillary lumen $(\times 18.400)$.

In the capillaries of untreated animals the endothelial cells completely covered the underlying basement lamina. Platelets were occasionally found in the lumen but there was no visible interaction between platelets and other blood cells nor between platelets and endothelial cells. Gaps appeared between endothelial cells in the very dilated capillaries of the animals which had been treated with reservine and of those which had been sympathectomized. The basement lamina thus became exposed at several points and was in direct contact with blood elements. At the exposed site a platelet, but never another blood cell, was found in close contact with the basement lamina (Figs. 1 and 2). When there were small gaps in the layer of endothelial cells only the "foot-like" process of a platelet contacted the basement lamina; the body of the platelet dipped freely into the lumen. Wider areas of denuded basement lamina were in close contact with more than one platelet, but platelet aggregates as seen during the formation of platelet thrombi were never observed. Other ultramorphological signs of thrombi formation, such as platelet degranulation and fibrin formation, were also absent.

Thus it would seem that in certain physiological conditions platelets function as "bouche-trou" when for any reason the endothelial cells separate and the underlying basement lamina becomes exposed. It is reasonable to assume that this phenomenon is reversible, that is, whenever the endothelial cells move back to their original position they can displace the platelet.

Platelets also adhere to the denuded basement lamina when there has been no injury to the endothelial cells other than vasodilatation. It seems unlikely that substances which amplify the ability of platelets to adhere are liberated from these endothelial cells. Because of the morphological similarity of the interactions between basement lamina and platelet and between basement lamina and endothelium¹ it is suggested that both are mediated by analogous forces, perhaps an electrical attraction.

With respect to observations in experimental platelet thrombosis, it seems that only the interaction between platelet and platelet and the subsequent platelet degranulation are related to endothelial damage and the release of tissue factors. The interaction between platelet and basement lamina seems to be related to endothelial injury only in as far as the basement lamina becomes exposed. We therefore suggested that this interaction and that between platelet and platelet are mediated through two fundamentally different mechanisms and should be thought of as two different phenomena.

Absence of Testosterone in Urine of Rats

Camacho and Migeon¹ established that testosterone which had been recovered from the urine of normal subjects was largely conjugated with glucuronic acid. Recently, measurement of testosterone in urine after β-glucuronidase hydrolysis has been proposed as a satisfactory means of evaluating testicular function2 and testosterone produc-

tion³ in male subjects. Testosterone has been tentatively identified in testicular venous blood of the adult rat4. From this observation, it was suggested that testicular function in the rat could be assessed by the excretion of testosterone in urine. To test this hypothesis we used the method of de Nicola, Dorfman and Forchielli⁵ to measure testosterone in urine. We modified their method to provide increased sensitivity, precision and specificity. The most important changes were: (1) acetylation of testosterone after paper chromatography, followed by thin-layer chromatography of testosterone acetate on silica gel in ligroin : ethyl acetate (5:2); and (2) addition of cholesterol as an internal standard before gas-liquid chromatography using 3 per cent OV-1 and 3 per cent OV-17 as the liquid phases on separate 6 ft. columns. In optimal conditions, 12.5 mug

biological samples. The results of our measurements of testosterone in urine are shown in Table 1. Testosterone was not identifiable after β-glucuronidase hydrolysis of urine which had been collected from adult rats or from rats which had been given human chorionic gonadotrophin. Urine from

of testosterone acetate was detected and measured in

a normal male subject and from a male pseudohermaphrodite gave results comparable with those reported by others5,6.

An attempt was made to determine whether a testosterone conjugate which could be hydrolysed by acid was present in the spent urine from adult male rats. After incubation with β-glucuronidase and extraction, the spent urine was taken to pH 1 with hydrochloric acid and incubated for 24 h (ref. 7) and analysed as described. testosterone could be identified. We concluded that little or no testosterone was present in the β-glucuronidase-hydrolysed or pH 1 fraction of urine from adult male rats or in the fraction from the urine of rats treated with human chorionic gonadotrophin which had been hydrolysed with enzyme.

Fishman and Sie⁸ demonstrated that slices of rat liver can conjugate testosterone with glucuronic acid in vitro. Comparison

Table 1. COMPARISON OF TESTOSTERONE EXCRETION IN URINE OF THE RAT

Experiment	Time of urine collection (h)	Recovery of *H-testo- sterone (%)	Testo- sterone measured (µg)	Calculated maximum testosterone/ sample (µg)
Twelve rats (250 g) Ten rats (80 g) 200 IU human chorionic gonadotrophin daily for 5 days	48 72	31·4 27·4	0	<0.281 <0.347
Normal man, aged 21 yr Male pseudoherm-	24	43.0	61·6/24 h	
aphrodite, aged 14 yr	24	29-9	66·0/24 h	

of the excretion of testosterone by the rat and man indicates that, although testosterone may be a secretory product of the rat testes, it does not seem to be excreted as testosterone glucuronide in the urine of the rat as it is in man.

Mode of Early Shell Growth in the Ammonite Promicroceras marstonense Spath

Some authors have suggested that the nature of the contiguity between the ammonoid proseptum and the shell wall indicates that there is no junction, but that the two are continuous resulting from contemporaneous formation1-3. This contrasts with the relationship between "normal" septa (that is, all septa excluding the proseptum) and the shell wall to which they are attached. There is abundant evidence in the case of "normal" septa that they were secreted by the animal's adapical soft parts to the inner surface of previously formed shell. The

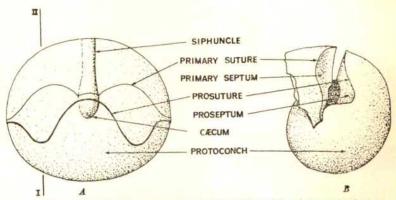

Fig. 1. Internal mould of the protoconch and early chambers of *Promicroceras marsionense* Spath: specimen No. DP 35. A, Ventral view showing the siphuncle and caecum which, although internal, can be seen through the transparent calcite infilling. The line I-II shows the approximate position of the sections illustrated in Fig. 3. B, Side view: the caecum has been omitted from this illustration. (×80.)

time relationship between each septum and the shell to which it is attached will therefore be the amount of time the animal takes to secrete shell proper equivalent in length to its body chamber, as shown for Nautilus pompilius Linné by Eichler and Ristedt⁴. Other authors⁵⁻⁸ maintain that the proseptum was inserted in an identical manner to normal septa. House⁶ (page 88) points out that the protoconch apparatus (prosiphon and caecum, Figs. 1A and 2E) is attached to the protoconch wall and must have been formed after this wall, but have preceded the proseptum.

During the present investigation, I prepared the nuclei of ten specimens of the Lower Jurassic ammonite *P. marstonense* preserved as aragonitic shells (determined by X-ray diffraction). The specimens were sectioned parallel to the median plane, to a position approximately mid-way between the median plane and the outer flank, in the region where the proseptum and primary septum are furthest apart (Fig. 1*A* and *B*). In exact median section the close proximity of these septa together with the bulbous caecum may confuse their interpretation (Figs. 1 and 2*F*).

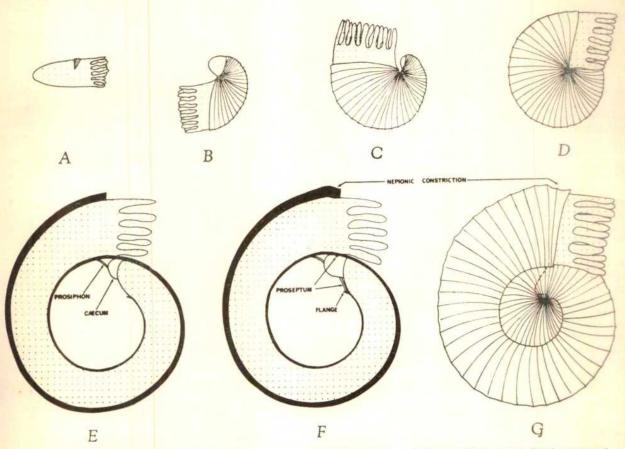

Fig. 2. Suggested mode of early growth of Promicroceras marstonense Spath, in particular, and of ammonoids in general. For the purpose of diagrammatic illustration the shell remains in the same position (A-G) and the soft parts are shown to revolve about the fixed shell. In life, the orientation of the entire animal would almost certainly have been different from that in the figure. Throughout the diagram, the lines on the shell are meant to represent growth lines; soft parts are stippled; shell (in E and F) is solid black. E and F are cross-sections in the median plane to show internal development. In G the position of the proseptum (dashed line) has been superposed on the shell. (All $\times c$. 68.)

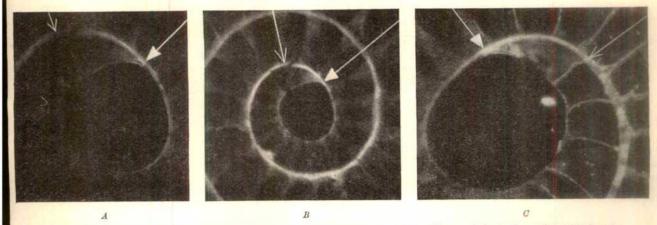

Fig. 3. Photomicrographs of polished nuclei of *Promicroceras marstonense* Spath. In A-C the solid arrow indicates the position of the junction between the proseptum and the inner shell wall, and the open arrow indicates the position of the junction between the primary septum and the inner shell wall. Sections are parallel to the median plane (see Fig. 1A). A and B, Specimen No. DP 25: $A_1 \times 100$; B_1 as A_2 , but with lower focus to show the convergence of the proseptum and primary septum towards the median plane (see Fig. 1B), \times 50. C_2 , Specimen No. DP 25, \times 100. In A_2 and A_3 the junction between the proseptum and the inner shell wall can be seen clearly.

The nuclei were highly polished and examined under reflected light. In several specimens the junction between the proseptum and shell wall could clearly be seen (Fig. 3A and C). This junction appears to be identical to that between all successive septa and the shell wall, and it is considered that the proseptum, of this species at least, was laid down by the adapical soft parts of the animal in a manner identical to that of all later septa.

In general, planispirally coiled ammonoids do not secrete a dorsal wall, unlike the nautiloids; shell secretion is therefore restricted to the venter and flanks of the animal. Invoking shell secretion from these areas only, it is shown how an ammonoid can produce the protoconch which houses the embryonic animal (Fig. 2). It is envisaged that the earliest formed shell is strap-like in shape and that this corresponds to the flange of the fully formed protoconch (Fig. 2A and F). Using only shell secreting glands situated at the adoral end of the soft parts, as in living Nautilus, the animal would be able to produce the protoconch in which it gradually encapsulated its soft parts. Growth lines on the protoconch of well preserved ammonoids are identical with those of the first whorl of growth ". . . and hence [the protoconch and phragmocone were] formed by shell secreting glands of similar type" (ref. 6, page 88). These growth lines indicate that the protoconch, like the phragmocone, was formed by the addition of successive shell increments.

It is considered that the protoconch actually housed the embryonic ammonoid and that after its formation the soft parts were permanently protected by shell. After secreting about three-quarters of a whorl of phragmocone shell, the prosiphon would be laid down, and this is followed by the caecum. After the completion of about one volution of phragmocone shell1,6,9-13, the nepionic It has been suggested that the constriction occurs. formation of the nepionic constriction by the adoral soft parts, and the secretion of the proseptum by the adapical soft parts, were contemporaneous. Eichler and Ristedt⁴ show that, for Nautilus pompilius, secretion of the proseptum may have preceded the formation of the "nepionic line" [=nepionic constriction]. As Erben' has pointed out, however, there are two important changes during early ammonoid ontogeny: the first occurs in the oral part of the protoconch, the second at the nepionic con-Both these changes are most convincingly shown in electron micrograph pictures by Birkelund¹⁴ for the species Saghalinites wrighti Birkelund. Erben relates the change in shell growth after the nepionic constriction with the change from the proseptum to "normal" septa, and suggests these changes indicate that the formation of the proseptum and nepionic constriction were contemporaneous. These changes are thought to indicate a metamorphosis¹⁵ in the ammonoids; the first as denoting the end of the embryonic stage (herein Fig. 2D), the second as ending the larval stage (herein Fig. 2G).

If this account of early ammonoid growth is correct, it would explain why ammonoids, which secrete shell in curved crescentic strips, do not have a cicatrix16, which is characteristic of the nautiloid apex formed by the secretion of successive concentric shell layers.

I thank Professor F. Hodson and A. Brandon for reading the manuscript, M. B. Attaie for the X-ray diffraction analysis and the Natural Environment Research Council for a fellowship.

Factor VII Deficiency in Beagle Dog Plasma and its Use in the Assay of Human Factor VII

During routine screening tests on a group of beagle dogs before a toxicological test, it was noted that several dogs showed a prolonging of the one-stage prothrombin time. Some of these dogs were found to be related (Fig. 1). The results of more detailed tests showed that intrinsic prothrombin activation was normal (Table 1) and that extrinsic prothrombin activation could be corrected by adding aliquots of normal human plasma or serum, normal dog plasma or serum, and Russell viper venom (Table 2). In addition, liver function tests were normal and the presence of an inhibitor was excluded (Table 3). Finally, factor VII activity assays, using congenitally deficient human plasma, confirmed that this factor specifically was reduced.

The use of the defective dog plasma in the assay of human factor VII requires an effective and readily obtainable thromboplastin. The obvious choice is human brain thromboplastin, which is in common use in most laboratories. The efficacy of this was compared with dog thromboplastin and shown to be adequate (Fig. 2). An incidental finding of interest here was that human brain thromboplastin was more efficient than dog brain thromboplastin in a normal dog system, and more sensitive to VII deficiency.

Dilutions, ranging from 1:10 to 1:1,000, of pooled normal human plasma were made with glyoxaline buffers and one-stage prothrombin times performed using 1:20 human brain thromboplastin in 0.025 molar calcium chloride and dog VII deficient plasma. Clotting times

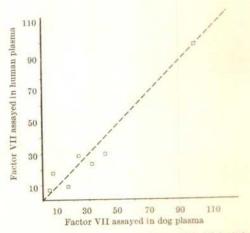

Fig. 5. Comparative VII assays in dog and human VII deficient plasmas,

were found to be shorter than predicted when the plasma concentration was less than 10 per cent. Dilution of thromboplastin did not affect this, but reduction of factor V content of the substrate plasma by incubating overnight at 40° C produced predicted values (Fig. 3). Comparing the assay of factor VII activity in diluted normal human plasma, using a known VII deficient human plasma and the deficient dog plasma with artificially depleted factor V, showed virtually identical results (Fig. 4).

So far, a comparison of seven factor VII assays, using human deficient plasma and the dog plasma, has been performed on patients under anticoagulant therapy or with liver failure. (The number of comparisons is limited by the unavailability of factor VII deficient plasma.) Good correlation has been obtained (Fig. 5).

It is suggested that this plasma provides a suitable substrate for the assay of factor VII in human plasma, a procedure until now dependent on access to a patient with the rare factor VII deficiency, or the less satisfactory methods involving the use of artificially depleted plasmas.

CYTOLOGY

Influence of the Injection of 'Triton WR-1339' on Lysosomes of a Rat Transplantable Hepatoma

Lysosomes are subcellular particles in which several acid hydrolases of various specificities are localized. One of their main intracellular functions is to digest exogenous compounds taken up by the cell. The lysosomal system can be overloaded with substances which cannot be degraded, at least at a sufficient rate, by hydrolases1. This occurs in rat liver lysosomes2 and to some extent in kidney3 and spleen lysosomes after injection of 'Triton WR-1339'. a non-ionic detergent. This compound is taken up by liver, kidney and spleen cells, and accumulates inside the lysosomes because it is not subjected to the lytic action of lysosomal enzymes. Accumulation causes increase in granular size and decrease in granular density.

This phenomenon can be used to study lysosomes in a tissue5. 'Triton WR-1339' has antitumoral activity6, and this has prompted us to investigate whether the detergent accumulates in the lysosomes of some tumours. We have used a chemically induced transplantable hepatoma in the rat (hepatoma HW) where a well developed lysosomal

system has been found7.8.

An injection of 'Triton WR-1339' causes a decrease in the equilibrium density of rat liver lysosomes in a sucrose gradient². The effect is also found in hepatoma lysosomes (Fig. 1). The distribution patterns of two acid hydrolases. cathepsin and acid phosphatase, which are reference

enzymes for lysosomes, after density equilibration in a sucrose gradient are shown in Fig. 1. The experiment was performed, using techniques similar to those of Beaufay et al.9 and de Duve et al.10, on a mitochondrial fraction isolated from hepatomas from a rat injected with 'Triton WR-1339' and from an untreated rat. The injection of Triton WR-1339' causes a striking shift of the distribution curves of the two hydrolases towards the low density

regions of the gradient.

The change may be explained by supposing that some of the injected 'Triton WR-1339' is stored in the hepatoma lysosomes as it is in liver lysosomes. An injection of Triton WR-1339' labelled with iodine-131 showed that some of the detergent was taken up by the tumour. After differential centrifugation using the method of de Duve et al.10, the radioactivity exhibits a distribution pattern comparable with that found for acid hydrolases (Fig. 2). A high percentage is associated with the mitochondrial fractions M and \bar{L} , and a peak of relative specific activity is found in the light fraction L. The most important difference is observed in the soluble fraction S, but this can be explained by a contamination of the homogenate with blood still containing radioactive deter-Proteins were measured by the method of Lowry et al.11 and radioactivity was measured in a liquid scintillation system using a Nuclear Chicago scintillator.

The radioactivity present in the mitochondrial fractions is not associated with mitochondria (Fig. 3). Cytochrome

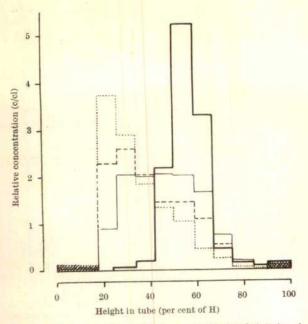

Fig. 3. Distribution of cathepsin (---), acid phosphatase (--), cytochrome oxidase (--) and radioactivity $(\cdot \cdot \cdot \cdot)$. Experimental conditions were as in Fig. 1. Mitochondrial preparation from a hepatoma of a rat injected with 170 mg of "Triton WR-1339" labelled with ^[41] and killed 4 days after the injection.

oxidase was measured by the method of de Duve et al. 10. After equilibration in a sucrose gradient, the radioactivity is associated with particles found in the low density regions of the gradient, where the lysosomes are localized as ascertained by the distribution of acid hydrolases. The detergent engulfed by hepatoma cells is therefore

probably confined in the lysosomes.

Because of the effect of 'Triton WR-1339' on lysosomes it is possible to label lysosomes with an exogenous substance, to produce an experimental overloading of the lysosomal system and to obtain a purified preparation of lysosomes. Results obtained on hepatoma HW suggest that rats injected with 'Triton WR-1339' may be used to study the lysosomes of the tumour. The detergent may have a similar effect on the granules of other tumours. The possibility of isolating purified preparations of lysosomes from the tumour would permit the analysis of their digestive capacities, of their membrane properties, of their immunological characteristics, and the comparison with lysosomes of normal tissue. The effect on a tumour cell of an overloading of its lysosomes could also be studied. The sensitivity of a cancer cell to injurious effect induced by overloading could be different from that of a normal cell.

Significance of Mitotic Spindle Fibre Orientation in the Neural Tube

CELLS in the neural tube are usually said to divide with their spindle fibres oriented parallel to the luminal sur-The plane of cleavage is always at right angles to the direction of the spindle fibres2, and so the cleavage between daughter cells would always be perpendicular to the luminal surface of the neural tube.

Examination of serial cross-sections of neural tube in early chick embryos, stages 14-20 (ref. 3), cut at 5μ and stained with haematoxylin and eosin, has revealed, however, that mitotic cells may have their spindle fibres oriented at various angles relative to the free surface of the tube. For example, the oil immersion photomicrograph in Fig. 1a shows a short segment from the neural tube of a twenty-two somite chick embryo-stage 14 (ref. 3), which contains four metaphase figures. Of these, the mitotic spindle fibres of cell A are clearly parallel to the luminal surface, but those of cells B and \hat{C} are obliquely oriented while the fibres of cell D are perpendicular to the luminal surface. Similar orientations of spindle fibres

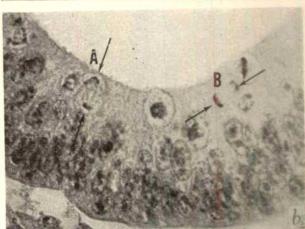

Fig. 1. Segments of cross-sections through the neural tubes of two twenty-two somite chick embryos; the arrows indicate the orientation of the spindle fibres. a, The spindle fibres of cell A are parallel to the free surface of the neural tube, those of cells B and C are oblique and the fibres of cell D are perpendicular to the free surface (\times 680). b. The spindle fibres of cell D are perpendicular to the free surface of the tube while those of cell B are parallel to the luminal or free surface (\times 640).

can be found at later stages of mitosis, for example, Fig. 1b, which shows a mitotic cell (A), in anaphase, with its spindle fibres perpendicular to the surface of the tube. The neuroepithelial cells which initially form the wall of the neural tube are attached to one another near the lumen by terminal bars and this terminal bar network remains intact during cellular division4-6. Thus when the cleavage furrow in a dividing cell is perpendicular to the luminal surface as in cell A (Fig. 1a), each of the daughter cells will receive part of the original terminal bar network and therefore probably remain attached at the lumen. When, however, the spindle fibres are oriented perpendicular to the epithelial surface as in cell A (Fig. 1b), the cleavage furrow will be parallel to the surface and it seems probable that the daughter cell furthest removed from the lumen will have no attachment to the terminal bar network. Such a cell would then be free to migrate away from the lumen and out of the epithelium.

If this is so, then the orientation of the spindle fibres is of considerable importance in maintaining, on the one hand, a population of proliferating neuroepithelial cells at the luminal surface of the neural tube and, on the other hand, providing a mechanism for the detachment of other cells during neuroblast differentiation. In this respect, it is no doubt significant that at the neural groove stage, before any differentiation of neuroepithelial cells is apparent, perpendicular spindle fibres are not found. With the appearance of neuroblasts, however, at about stage 14 of development3, spindle fibres perpendicular to the luminal surface are noted and remain apparent until approximately stage 20 (ref. 3), at which time most neuroblasts, destined to become motor neurones in the spinal cord, have been formed.

Action of Cytochalasin B on Cultured **Human Lymphocytes**

COMPOUNDS which effect cell division are interesting because they have the potential of increasing our knowledge about this poorly understood biological process. The cytochalasin compounds fall into this category because they can influence both cellular and nuclear division. Cytochalasins are metabolites derived from moulds, and have recently been isolated by Dr W. B. Turner and their molecular structure reported by Aldridge et al.1. Carter has shown some of the effects of the cytochalasin B on Earle's L strain of mouse fibroblasts in culture². In varying conditions of concentration and time, the compound inhibited cell motility, produced extrusion of the nucleus and blocked cytoplasmic cleavage, nuclear division continuing with the production of multinucleated

Some of the effects of these compounds seemed to be dependent on the culture environment of the fibroblasts, and so we decided to test the effects of cytochalasin B on human cells grown in suspension.

Peripheral blood was obtained by venipuncture and prepared for lymphocyte cultures, using a modification of the technique of Moorhead et al.3. Cytochalasin B was dissolved in dimethyl sulphoxide (DMSO) and refrigerated at 4° C as a 0.1 per cent stock solution. The stock solution

168	35	38				

was added, at the start of the culture, so that the final concentrations in the cultures varied between 0.5 to 20 μg/ml. The lymphocyte cultures were incubated for up to 7 days. At intervals, samples of culture were fixed in glacial acetic acid and absolute ethyl alcohol (1:3) and examined microscopically. Cells were spread on clean slides using the air drying technique of Rothfels and Siminovitch⁴. The cells were stained with Leishman's stain. Control cultures without cytochalasin and with DMSO added alone were set up.

There was initial failure of cultures because of an apparent toxicity of DMSO at certain concentrations. This was eliminated by keeping the final concentration of DMSO not greater than 0.1 ml. in 10 ml. of culture When the concentrations of DMSO and cytochalasin B were standardized, the lymphocyte responses varied only slightly in different cultures, and a general pattern was discernible.

Only an occasional multinucleated cell was seen in the cultures with a final concentration of cytochalasin B of less than 2 µg/ml. A significant response, as judged by the production of multinucleated cells (Figs. 1 and 2), was obtained when the compound was used at a final concentration of 2-20 µg/ml. (Table 1). There was increasing

response up to 6 µg/ml.

A very small proportion of binucleated cells were detected in the cytochalasin cultures up to 48 h, with a major response at 72 h rising to a peak at 96 h (Table 2). There seemed to be an increase of cells with more than two nuclei (Fig. 3) between 72 and 168 h (7 days). The

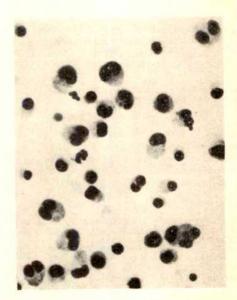

Fig. 1. Preparation showing chiefly binucleated cells after exposure to 6 μ g/ml, of cytochalasin B (\times 300).

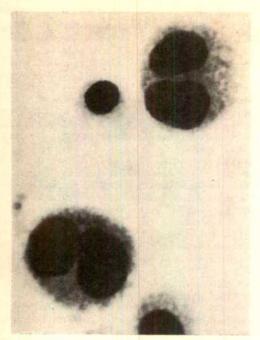

Fig. 2. Typical binucleated cells after exposure to cytochalasin $B = (\times 1, 264)$.

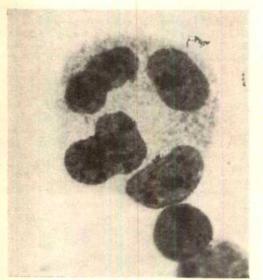

Fig. 3. Multinucleated cell showing variations of nuclear morphology (\times 1,264).

7 day cultures also showed evidence of cellular degeneration, probably secondary to nutritional depletion of the

Cells with between one and eight nuclei were clearly observed; however, it is possible that cells with more then eight nuclei were present. In some cells with more than three nuclei, it was difficult to determine the exact number because the nuclei were closely packed and there was some overlapping. The proportion of cells containing ncreasing numbers of nuclei was inversely related to the number of nuclei in each cell. In many multinucleated cells, the nuclei varied in size and shape (Fig. 3), and nicronuclei and nuclear bridging were seen. Cytoplasmic bridging also occurred but much less frequently than nuclear bridging. Only rarely was nuclear extrusion letected.

While this study of the effects of cytochalasin B n cultured human lymphocytes demonstrates that the compound produces multinucleated cells, and is in agree-

ment with some of the observations of Carter for mouse fibroblasts, there are certain important differences. Lymphocytes required a higher concentration (2-6 µg/ml.) of cytochalasin than fibroblasts (0.5–1.0 µg/ml.) in order to produce multinucleated cells. Nuclear extrusion could easily be observed and controlled in mouse fibroblast cultures, but this phenomenon was only rarely observed and was unpredictable in lymphocyte cultures. Based on Carter's observations, it seems unlikely that a difference in dosage could totally account for lymphocyte cultures only rarely showing this phenomenon. A more likely explanation might be based on different growth patterns of the two cell types. Mouse fibroblasts are cultured as monolayers while lymphocytes are grown in suspension. Carter has postulated that extrusion of nuclei is related to a surface tension effect on the cellular membrane of the growing fibroblast.

The nuclei in dividing multinucleated cells appeared to be in the same stage of mitosis, although in some cells the dividing nuclei were slightly out of phase with each other. There were no mitotic figures associated with an interphase nucleus (asynchronous division). Carter has used the term "pseudomitosis" to account for the observation that the nuclear complement of each cell increases by increments of one nucleus instead of the doubling which would be expected with a failure of cytoplasmic cleavage. Lymphocytes also appear to show a gradual build-up of the number of nuclei per cell, and cells with between one and eight nuclei have been defined. The observed variations in the size and shape of the nuclei are difficult to explain by the "pseudomitosis hypothesis" alone. Mitotic figures often showed disorganized aggregates of varying numbers of chromosomes which may be related to the morphological variations seen in interphase nuclei. Evidence from mitotic figures suggests that, at least in some cells, variation in nuclear morphology may be due to abnormal division of the chromosomes with multipolar mitotic apparatus, for binucleate cells of normal appearance were produced after the first nuclear division. While it may be possible to postulate other effects of the compound on the mitotic apparatus, there is no direct evidence, at this time, on the specific mode of action of the compound in producing the observed variation in nuclear morphology.

We thank Dr S. B. Carter for supplying us with the cytochalasin B compound, and the Association for the Aid of Crippled Children for financial support.

BIOLOGY

Longevity of Rhinolophid Bats

Numbered aluminium bands which are used to study the movements of bats are also of value in providing specific information concerning age1. In Britain, the first large scale bat-banding experiment was commenced in Devon in 1948 (ref. 2) and during recent years it has been gratifying to note the continued survival of a number of

greater horseshoe bats (Rhinolophus ferrumequinum) banded during the early stages of that experiment. Of particular interest has been the finding, on October 28, 1967, of greater horseshoe No. 918 (male). This bat, found in a small mine adit near Holne, in south Devon, was originally banded in a cave at Buckfastleigh, about 3 miles away, on March 4, 1949. Its age, when first handled, was not known, but because for this species birth invariably occurs only in mid-summer, usually early in July, this bat could not have been born later than July 1948. At the time of its most recent finding it must therefore have been at least 19.25 yr old.

This is the greatest age so far recorded for a Rhinolophid or indeed for any other species of bat in Britain. It seems probable, however, that such longevity, at least for R. ferrumequinum, may not prove unusual for during the past 3 yr two ringed bats of this species aged at least 17.5 yr and a further six individuals aged at least 16.5 yr

have been recorded in Devon.

"Booby-trapping" as an Alternative to Sterile Males for Insect Control

ATTEMPTS are now being made to apply to other pests the sterile male technique, so successful in the suppression of the screw-worm fly Cochliomyia hominivorax in the southern United States. There is, however, a need to devise similar methods which may be even more appropriate in particular cases. One such method which is similar to, but simpler than, the "booby-trapping" method of Morgan¹ was suggested as a result of experiments with the Australian sheep blowfly, Lucilia cuprina. Female flies, resistant to dieldrin, which survived 0.5 µl. of 2 per cent dieldrin dissolved in kerosene and diisobutyl ketone (1:1) applied topically to the thorax, were exposed to males from a susceptible strain (LD_{50} < 0.005 per cent dieldrin). Each female killed up to one hundred males through contact during attempted mating. Treated resistant males were capable of killing susceptible females, but the effect was of a lower order of magnitude.

How might this sort of system be used for insect control? There are clearly a number of possibilities of which we shall mention two. The most obvious is to take advantage of the development in one region of a strain of pest resistant to a particular insecticide, or to develop such a strain in the laboratory. These resistant insects could then be mass reared, sterilized, loaded with the insecticide to which they had become resistant, and released among susceptible populations. Another possibility is to load insects with a non-lethal topical dose of a stable chemosterilant, of such a type that it will nevertheless exert a sterilizing effect on the carrier itself and also on those with which it mates or attempts to mate.

There are several points worth noting in a system of this sort. (a) Instead of females being of no particular advantage, as in the case of the screw-worm fly, both sexes are effective in destroying or sterilizing their partners. (b) Multiple matings are an advantage. In species in which the female tends to mate once only, attempted matings by males treated with insecticide will destroy a female even though copulation is not achieved. In the sterile male technique the reproductive capacity of fertilized females is not influenced by attempted matings by sterile males. (c) Relatively minute quantities of insecticide are employed, thereby reducing the danger of accumulation of toxicants in soil and water. (d) Tl range of possible insecticides is increased, because que tions of toxicity to man and domestic animals are large irrelevant.

There are several problems inherent in the use of resis ant insects in a "booby-trap" method. Thus, as a resu of incomplete sterilization, genes for insecticide resistan might enter the gene pool of field populations. Th probability of this could be minimized by supplementing sterilization with other systems, such as condition lethals, perhaps governing nutritional requirements f the released strain.

If resistance to a pesticide has developed in one regie it is very likely to emerge also in other regions und selection pressure. Its development might be delaye however, if the strain released were selected to be "supe resistant" so that the wild, susceptible individuals wou tend to encounter a lethal dose of the chemical if the were exposed to it at all.

If a choice were available the genetic basis of the resistance itself would also be an important factor f consideration. Resistance which is polygenic at balanced, as described by Crow2, would seem to be mo difficult to incorporate accidentally into the field popul tion. Chance outcrossing of resistant to susceptib strains would probably destroy the particular combination of genes necessary for resistance.

By contrast, the use of an appropriate chemosterila

seems not to involve any of these disadvantages.

The "booby-trap" technique seems particularly suits to insects with the following characteristics: (a) amen bility to cheap laboratory propagation; (b) a low natur population density; (c) the adult stage not attracted humans (if highly toxic insecticides are to be employed (d) behavioural characteristics leading to consideral and frequent bodily contact between individuals-1 example, a readiness of males to attempt mating with females encountered.

The Australian sheep blowfly possesses all these chara teristics. In species where the adult constitutes the 'nuisance' stage the sterile male method may be und sirable because of the need to flood the natural population with ten or more times the number of sterile insect If, however, the killing power of insects loaded with chem sterilant or insecticide is sufficient, the "booby-traj method may be practicable because it would not be nece sary to release nearly so many individuals.
We thank Dr D. F. Waterhouse for helpful criticism

Regeneration of the Axial Organ of Arbacia punctulata and its **Implications**

LITTLE is known of the regenerative powers of echinoic so that it is of interest to report the regeneration of the

most enigmatic organ.

The axial organ is a complex spongy structure lying the mesentery which carries the oesophagus. The lor standing controversy over its function has recently be revived by the studies of Boolootian and Campbell¹ Millott and Vevers³, Millott^{4,5} and Farmanfarmaian⁶ So far, only one function has been adequately demo strated, namely, activity in defence against injury as

infection⁴. The axial organ has often been regarded as a heart and, despite evidence to the contrary^{3,6,7}, the idea dies hard.

One argument against such a view stems from the fact that urchins can survive complete removal of the organ^{3,8}. Our studies of its regeneration in *Arbacia* amply confirm this. More significantly in this connexion, we have shown that animals so treated usually remain healthy and active. No case therefore remains for regarding this structure, or any part of it, as an important circulatory organ in the accepted sense of the term.

Axial organs with their attendant "head processes" were excised through the small hole in the test remaining after removal of the madreporite. If animals so treated emain in highly aerated running sea water the wound soon heals and the axial organ is usually regenerated Figs. 1 and 2) although not necessarily completely or orecisely in its original form.

The "head process" is reformed independently of the est, the regeneration of which is preceded by de-differntiation and histolysis of the remaining portions of the

stone canal and mesentery. This is accompanied by active proliferation and migration of cells within the mesentery, so that a blastema is formed, which receives contributions in order of decreasing importance, from the surrounding peritoneum, the lining of the stone canal and the so-called haemal vessel of the mesentery. Cellular de-differentiation is extensive (Fig. 3), yielding fusiform cells which migrate in such numbers that they often denude the stone canal and mesentery, respectively, of lining and covering.

The migrating cells fuse to form a stroma of delicate fibrous connective tissue within the blastema forming a plate- or cup-like rudiment (Figs. 4 and 5). Some of these cells become greatly distended by vacuoles or pigment and their subsequent disintegration produces deep stromal fissures in which amoebocytes and impressive quantities of pigment accumulate.

Cells derived from the peritoneum and lining of the stone canal now align to form strands or tubes which invade the stromal fissures (Fig. 5). In the case of cup-like rudiments the stroma is invaded from both the outside and the hollow interior (Fig. 5). Cells invading from the

outside come to line pre-existing spaces forming canaliculi⁵, and also contribute, together with any haemal elements remaining in the mesentery, to the contents of the lacunae⁵. Cells invading the hollow of the cup assemble on its surface as a dense mass of strands or tubules, some of which, destined to enclose the ramifying channels of the contractile vessel⁵, extend to join the lacunae forming within the stroma. Others penetrate the stromal fissures which they come to line and so form the characteristic embayments of what will become the central lumen of the organ⁵.

The process of reconstituting the stone canal has yet to be discovered. The extent to which it disorganizes seems to influence both the level at which the organ is regenerated along the oral-aboral axis of the mesentery and the form of the early regenerate. There are hints of a morphogenetic influence, for in the two cases where there was no evident regeneration, little, if anything, could be found of the canal.

The work was in part supported by a grant from the US National Science Foundation to the Department of Invertebrate Zoology at the Marine Biological Laboratory,

Nature of the Magnetic Radula in Chitons from Eilat on the Red Sea

Ir has been noted^{1,2} that the radula (rasping tongue) o certain chitons, molluscs, are ferromagnetic. Examples o Polyplacophora in which the magnetism is reported to be caused by magnetite in the dentical caps are species of Cryptochiton, Chiton, Acanthopleura, and Mopalia1 and Chaetopleura apiculata².

We have studied the radula of Acanthopleura haddoni the largest intertidal species to be found at Eilat on the Red Sea coast, and have found that it is ferromagnetic The magnetic moment measured at room temperature was found to be 7 EMU/g of radula; for the dentical cap at a magnetic field of 10 Koersteds, it is more than 75 EMU/g. The Curie point is 570 ± 5° C. Hysteresis curves at room temperature and dependence of magnetization on temperature are shown in Figs. 1 and 2, respectively. All magnetic measurements were made on a motor-driven vibrating sample magnetometer.

There was an irreversible loss in magnetic moment on heating (see Fig. 2), and also when the samples were heated to 600° C in a helium atmosphere. A long and wide ferromagnetic resonance (full width at half height approximately 500 oersteds) absorption was found as expected; measurement was carried out at the X-band.

X-ray diffraction photographs were taken with a Norelco 'Straumanis' camera, with a diameter of 114.6 mm and cobalt radiation filtered through an iron foil. The pattern shows the existence of a spinel phase with a unit cell of 8.400 ± 0.003 Å. It is of interest that no magnetic phase other than that of the same spinel with the unit cell of 8.398 ± 0.003 Å appeared after the specimens had been heated to 500° C.

The magnetic and crystallographic data are on the whole consistent with the magnetic properties and the crystal

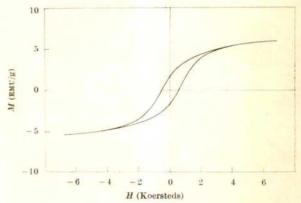

Fig. 1. Magnetic hysteresis curve of radula,

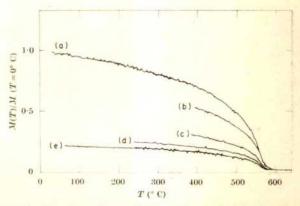

Fig. 2. Dependence of magnetization on temperature at subsequent measurements. a, First; b, second . . . e, fifth. Further cycles do not essentially change the magnetization.

structure of synthetic magnetite (Fe₃O₄) (ref. 3). It should be noted, however, that while the reduction of the magnetic moment on heating in synthetic magnetite is caused by oxidation to ferric oxide, this is probably not the case with Acanthopleura haddoni.

We also found that the remanence in virgin state of the radula was less than 0.1 per cent of the maximum remanence (that is 30 EMU/g) in this material. This negates, in our opinion, the speculation that the magnetic material might serve as a guidance device for navigation1.

Non-thermal Effects of Microwave Radiation on Birds

MICROWAVE radiation produces both thermal and nonthermal effects in biological systems^{1,2}. The thermal effect is manifested as a rise in temperature of the irradiated system and is accompanied by physiological responses depending on the intensity and duration of the field. Non-thermal effects are manifested as changes in cellular metabolism caused by both resonance absorption and induced EMFs and, when neural structures are involved, are often accompanied by a specific behavioural response. An important difference between thermal and non-thermal effects is in the matter of time scale. Chickens exposed to a "slightly thermal" microwave field (20-50 mW/cm2) respond with an escape or avoidance reaction within a few seconds of the onset of radiation3.

The rapidity and compelling nature of this reaction led us to investigate microwaves in relation to the bird strike problem which is now reaching serious proportions in airline operations. Experiments are being conducted to determine the effectiveness of microwave radiation as a means of deterring birds from feeding in the vicinity of airport runways and of dispersing birds from commercial flight lanes.

The physiological correlates of this behavioural pattern have been studied to develop the escape reaction further and to determine the most effective form of microwave field. Experiments were conducted on three species of chickens using a 9.3 Gc/s microwave generator pulsed at 416 p.p.s. with a pulse width of 2.3 usec. Peak power into the horn antenna is 94 kW and the average power is correspondingly 90 W. The field intensity in the calibrated

test cage at a level 6 in. above the floor is set at 46 mW/cm² (average value).

The general pattern of behaviour of both young and fully grown chickens in the test cage is as follows. At the onset of radiation the wing outside the field of radiation becomes collapsed and the opposite wing is extended. A

similar phenomenon is observed with the legs. chickens incline their heads so that the eye closest to the field of radiation is oriented to the field and the sagittal axis of the head is kept in line with the appropriate axis of the body. The bird turns down to the outside of the field following this axis of the body. It is apparent that in this turning reaction the outer side of the animal is paralysed and on reaching the floor of the cage the reaction is manifested by increased extensor reaction of the inner (field) side and the head is turned to face the centre of the field.

On occasions this pattern of behaviour has not occurred and the following observations have been made. It seems that some animals present a hyperactive side. When these animals are radiated with the weak side facing the centre of the field they rapidly orient themselves to present the strong or hyperactive side to the field. The previously described behavioural pattern then ensues. Some birds are excited at or before the time of radiation because of outside influences, for example, handling, change of cage. These animals continue to be excited and at the onset of radiation move along the field so that one side of the head and body will be alternately outside and inside the field. Chickens in these conditions either reach a terminal state in the experiment by remaining quiet for a few seconds and then collapsing to the corresponding side, or in their agitation initiate flight.

During all these experimental procedures we have observed that different reactions can be obtained from a bird depending on which surface is irradiated. little or no reaction is detected if the bird is irradiated from below, thereby affecting its ventral surface. When irradiated from above, however, a clear distinction has been observed between the distal dorsal and tail regions of the animal and the head, and the neck to proximal dorsal regions. In the first case, an excitatory effect is obtained which can lead to the animal changing position or flying. The second case usually ends in a collapsing action as previously described.

Bacteria-free Culture of Oyster Larvae

LARVAL cultures of many marine bivalve molluses have been maintained through stages leading up to metamorphosis and the principal requirements are now known, particularly for the European oyster Ostrea edulis L., the American oyster Crassostrea virginica (Gmelin) and the American clam Mercenaria mercenaria (L.). It is common experience that cultures may fail unexpectedly and there is evidence that bacterial contamination is often the cause^{1,2}. In this laboratory we have also had inconsistent results and sudden mortalities, and have found that bacterial counts vary greatly and are often high, even when antibiotics are used. Although antibiotics reduce the percentage of failures, Hidu and Tubiash² have shown that streptomycin, which is commonly used for this purpose, can increase the total bacterial number; its beneficial effect is to limit harmful bacteria and to increase useful types. The use of antibiotics leads to levels of success that would be acceptable in hatchery work, but it

is evident that critical experiments in larval nutrition, in genetic and environmental effects on growth and other aspects of larval biology, will depend on the elimination of the variable factor represented by the presence of bacteria. We have therefore investigated methods of growing the larvae of O. edulis in the absence of bacteria.

Hidu and Tubiash obtained bacteria-free fertilized eggs of M. mercenaria by repeatedly washing them in sterile sea water and the larvae were then maintained in aseptic conditions. In the absence of added algal food, however, there was little growth. O. edulis is larviparous, and in order to purify the larvae, which have a functional gut probably containing bacteria, we used strong antibiotic solutions as suggested by Droop⁴. One of several successful methods which we used was to allow larvae to swim for 48 h in a mixture of 670 µg/ml. of penicillin, 50 µg/ml. of streptomycin and 5 µg/ml. of chloramphenicol, made up in sterile sea water. The larvae were then washed for 1-2 h in sterile sea water to remove the antibiotics. Larvae were transferred to a series of test tubes each containing 25 ml. of autoclaved sea water and sufficient sterile culture of the flagellate Monochrysis lutheri Droop, to give a final concentration of about one hundred cells/mm³. The tubes were plugged and maintained at 20° C. Algal food was added aseptically to the tubes after 6 or 7 days. Tubes were finally opened in succession and sterility tests were made by incubating nutrient media which had been inoculated with material from the test tubes. Larvae were then measured.

Thirteen out of seventeen tubes thus treated were sterile. The fastest growing larvae increased in length by about 10 µ/day and after 22 days had eyes, indicating that development was complete. After 22 days, five out of ten sterile tubes contained larvae which had eyes and the highest percentage in a tube of larvae with eyes was 20 per cent. Few larvae died, and the total mortality was 0.6 per cent. In all tubes there was a wide range of larval sizes and this is a feature also found with the more usual method of culture. growth rates in our experiments were somewhat less than the fastest recorded rates in routine contaminated cultures which had been given frequent changes of water and carefully controlled concentrations of mixed algal diets. In our experiments, food concentrations were probably far from optimal; larval densities were sometimes too high and it is possible that accumulated waste products also retarded growth.

This work has established that oyster larvae can be rendered free from bacteria and can subsequently be grown to settling size on a pure algal diet of *Monochrysis lutheri* and do not need bacteria. With this aseptic technique, it should be possible to control much more closely the conditions in experiments with oyster larvae.

Growth and Partial Metamorphosis of Imaginal Disks of the Greater Wax Moth, Galleria mellonella, in vitro

The most important of the problems of insect metamorphosis is the nature of the action of ecdysone. There is a particular lack of knowledge of the stages between the initiation of metamorphosis by ecdysone and the final

differentiation into the adult. Experiments on the action of pure ecdysone *in vitro* have been conducted with systems which respond in a limited way to ecdysone but do not grow or metamorphose^{1,2}. This communication reports the initiation of metamorphosis in an insect tissue by pure ecdysone *in vitro*.

Encouraged by the successful culture of eye-antennal disks of *Drosophila melanogaster in vitro*³, we cultured wing disks of *Galleria mellonella* in the hope that they would also grow and differentiate. This organism was chosen because it is easily reared in the laboratory; because the wing disks are large in comparison with the imaginal disks of *Drosophila* (giving promise of biochemical analysis); and because a great deal of attention has already been paid to the endocrinology of the lepidoptera.

In our conditions for growth, larvae spun eocoons 7-8 days after the last larval moult4. Donor larvae were washed in 70 per cent ethanol for 1 min, and rinsed twice in sterile insect Ringer⁵. The disks were dissected out in Ringer solution and transferred to Grace's tissue culture medium (Grand Island Biological Co.). After two rinses in sterile medium the disks were cultured in sterile plastic Petri dishes $(35 \times 10 \text{ mm}, \text{Falcon Plastics})$ which contained 0.5 or 0.7 ml. of Grace's medium plus 5 per cent lobster haemolymph (Grand Island Biological Co.). In several cases the haemolymph was left out of the medium with no apparent effect on the cultures. Most cultures were kept for 4 weeks, during which the medium was not replaced. The following results are based on observations of 145 cultured wing disks. No distinction was made between first and second wing disks in these experiments.

Wing disks from larvae which weighed between 0.25 and 0.30 g (within 1 day of cocoon spinning) were cultured if their tracheae had begun to spread out from the localized tracheal mass characteristic of younger undifferentiated disks. Twenty-seven out of thirty-one such wing disks exhibited continued tracheal spreading and growth after only 24 h in vitro. The length of these disks increased from about 1 mm to 2 mm within 2 weeks, but did not increase after that (length measured with an ocular micrometer was used as a convenient parameter of growth in these experiments). Furthermore, the disks became more wing-like and frequently formed vesicular outgrowths, which are characteristic of insect organ cultures. By contrast only four out of forty-five disks from larvae which weighed from 0.1 to 0.2 g had initiated metamorphosis even after 1 month of culture.

If ecdysone is the only extrinsic agent necessary for metamorphosis, then its addition to cultures of disks which would not otherwise grow should cause them to grow and metamorphose. To test this, ecdysone (1 µg/ 10 μl. of 10 per cent ethanol) was added to 0.7 ml. of medium in Petri dishes. The following doses were used with equal success: 1·5 μg, 2 μg, 5 μg and 10 μg. An equal amount of alcohol was added to control cultures. (Ecdysone (2 µg) from the same source was sufficient to initiate metamorphosis in brainless pupae of $Hyalophora\ cecropia^7$.) Disks were taken from larvae weighing 1.5-3.0 g. Those disks which had already initiated metamorphosis were discarded. Each group of four disks from a single larva was divided equally between control and experimental cultures. Between 3 and 10 days after the addition of ecdysone twenty-six out of thirty-five disks had initiated metamorphosis, while in the control group without ecdysone only three out of thirty-four had done so. Vesicles were found infrequently in the disks treated with ecdysone, although they were common in disks which grew without ecdysone in the medium.

Thus we have found that wing disks of Galleria mellonella will grow and partially metamorphose in vitro if metamorphosis has already begun in vivo, but will not do so otherwise unless ecdysone is present in the culture medium. Clearly, ecdysone alone is responsible for the initiation of metamorphosis in these disks in vitro. Why the wing disks do not complete their growth and dif-

ferentiation in vitro, and why ecdysone takes several days to produce a visible change in the cultures, is not yet known. Nevertheless, we hope that this system will be useful in investigating the action of ecdysone in vitro.

This work was supported by the US National Science Foundation. We thank Dr Alexander Cross for ecdysone, and Dr Howard A. Schneiderman for a starter culture of Galleria mellonella.

Short Term Cultivation of Trypanosoma brucei in vitro at 37° C

STUDIES on the African pathogenic trypanosomes have been severely hindered by the failure of the infectious forms of these organisms to grow in vitro. All previous reports of the cultivation of the African trypanosomes refer to non-infectious forms resembling those found during the multiplication of the flagellates in the insect vector (Glossina sp.). Occasional infectivity of such cultures has been reported¹⁻³. This communication cultures has been reported1-3. describes the occurrence of a short term multiplication which occurs when trypanosomes are separated from infected blood and maintained at 37° C in the supernatant fluid over a monolayer of L-cells.

Tissue cultures of the mouse L-cell line were prepared in 8 oz. screw-top medical flat bottles. L-cells were inoculated into 5 ml. of medium and the cultures were incubated at 36°-37° C until confluent monolayers were established. The medium used for cell and trypanosome/cell cultures was NCTC 109 (Difco Laboratories) containing in addition 10 per cent v/v pre-sucking calf serum, 50 μ ml. penicillin and 50 μ g/ml. dihydrostreptomycin. NCTC 109 was used empirically. The gaseous phase consisted of air in some experiments and of 5 per cent CO_2 , 10 per cent O_2 and 85 per cent N_2 in others⁴. Ninety-five per cent O2 with 5 per cent CO2 was harmful to trypanosomes.

A Parkes strain female mouse was inoculated with the Lister strain 427 of T. brucei. Approximately 105 infectious organisms were inoculated into the peritoneal cavity of the mouse so that between 10⁷ and 10⁸ organisms were present for each ml. of blood after 48 h. The mouse was bled from the heart under light ether anaesthesia and the blood was diluted four-fold with warm medium ($30^{\circ}-35^{\circ}$ C) and defibrinated by rotation with glass beads. The blood

was transferred to a centrifuge tube and further diluted two-fold with more medium. The blood cells were deposited by centrifugation at 250g for 4 min and the supernatant containing trypanosomes was removed. The number of trypanosomes was adjusted to 2-6 × 105/ml. of medium and 5 ml. of this mixture was inoculated into each tissue culture bottle from which the medium had been decanted just before use. Aseptic precautions were observed throughout the procedure. Samples were removed at intervals for counting without dilution in a Neubauer haemocytometer. Organisms prepared in this way multiplied about threefold in vitro with a generation time of 6-9 h. Significant increase was never observed in control bottles without L-cells, but dividing forms were often present. The success of any culture varied in particular with the origin of the organisms in relation to the phase of growth in the donor animal, the serum component of the medium and the pH of the medium. Organisms taken from near the peak of parasitaemia in the donor animal were much less consistent in multiplying in vitro. It is not certain whether this result was a simple function of the stage of the growth cycle because the use of organisms from late in the growth cycle involved greater dilution of the infected blood and increase in numbers was not consistent when organisms were washed by centrifugation The pre-sucking calf serum was and resuspension. superior to normal rabbit serum, but not all samples of calf serum were equally satisfactory and selection of a suitable serum was initially necessary. Precise experiments on the effect of pH were not possible in the system described, but values below pH 7.2 or above 7.6 inhibited multiplication. Animals could be infected regularly with organisms from 24 to 36 h cultures and occasionally up to 70 h. Multiplication usually ceased after 20-30 h and attempts to subculture the organisms before this time gave most variable results. Even the division of the supernatant fluids into two and their replenishment with fresh medium often inhibited all further increase in numbers. The organisms present after 24 h or more were more easily damaged by centrifugation or pipetting than the original inoculum. Multiplication after subculture was observed after 12 and 24 h in a few instances when the culture bottles were tilted slightly, allowed to remain like this for 2 h and the top 3 ml. of medium removed and replenished. This contained only a third of the total number of organisms present. Preconditioning of medium in the presence of L-cells did not favour further multi-The supplementation of the medium with plication. washed mouse red cells, mouse or rabbit red blood cell lysate, or with haemin in varying concentrations down to μg/ml., inhibited or severely reduced multiplication.

Table 1 and Fig. 1 show the results of an experiment in which five-fold multiplication was observed. In a series of twenty similar trials the mean multiplication observed in the presence of L-cells varied from none (four experiments) to five-fold (three experiments), with the remainder showing a regular three-fold increase. In the absence of the L-cells, the trypanosomes frequently declined in number rapidly from the beginning of the experiment.

A preliminary study of the incorporation in vitro of radioactive leucine, thymidine and uracil into trypano-

§ Contaminated with bacteria.

somal protein and nucleic acids, carried out in conjunction with Dr B. A. Newton, showed that linear uptake of these substances occurred over the 6 h period studied. There were no significant differences between the incorporation rates in the presence and absence of L-cells. Test and control cultures could readily be distinguished at 18 h, however, by the superior survival and normal appearance of the organisms in the L-cell cultures as compared with the controls. The lack of measurable differences in the incorporation rates may have resulted from the high cell densities used in these studies, which effectively prevented multiplication. L-cell cultures were chilled at 4° C for I h before use in order to reduce the synthesis of DNA in these cells. Supernatant fluids were free of detectable L-cells, provided newly confluent monolayers were hearr

It is evident that these results represent only a very limited success in cultivating trypanosomes because the multiplication seems to be as dependent on the use and preparation of a suitable trypanosome population as on the conditions of the culture. It is not, however, strain dependent, because all the four strains of T. brucei tested seemed to react similarly. Although complex, the system seems to offer the opportunity of examining the nutrient requirements of trypanosomes in conditions in which the base line for comparison represents an increase rather than a decrease in numbers. No conclusions can be drawn from these experiments about the nature of the dependence of the multiplication observed on the presence of the L-cells, but this might be further investigated by the pre-treatment of the L-cells with metabolic inhibitors affecting pathways absent from the trypanosomes, or by the irradiation of the L-cells with X-rays or ultraviolet light. The finding that multiplication could be obtained but not indefinitely prolonged might suggest that in addition to the dependence of the multiplication on the L-cells the explanted organisms contain a pool of an essential metabolite sufficient for a limited number of cell divisions and lacking from the medium used. Several other explanations are, however, possible. The fact that all these experiments were carried out at 37° C, that there was no observable lag phase at the start of the cultures and that significant (more than two-fold but less than three-fold) multiplication of an akinetoplastic strain of T. evansi could be observed in the same system supports the belief that these results represent multiplication of the blood form of a pathogenic trypanosome rather than the appearance in unusual circumstances of other stages of the life cycle. More precise studies on the nutritional requirements of these parasites are needed.

Accumulation of Nitrite in Fresh Soils after Gamma Irradiation

Large increases of plant growth in irradiated soils have been attributed principally to increases in available ammonium- and nitrate-nitrogen1 although the accumulation of nitrate in fresh and dry soils has not always been observed^{2,3}. Experiments by Cawse⁴ have consistently shown substantial increases in nitrate when five fresh soils were incubated after treatment with 1.5-200 × 10³ rads.

To establish the point at which oxidation of ammonium to nitrate begins to be diminished by radiation, the soils previously described4 were irradiated with increasing doses up to 1 × 106 rads; during the course of this work it was noted that nitrite, as well as ammonium and nitrate-nitrogen, accumulated rapidly after one soil (Broad Series) had received 5×10^5 rads. A similar organic calcareous soil (pH 7·4 in 0·01 molar calcium chloride) was obtained from the Icknield Series⁵ for irradiation, and it, too, accumulated nitrite. Only ammonium- and nitratenitrogen showed increases in the other four soils, even when the dose was extended to 2.5 × 10° rads; data for Grove Series are representative of this group.

The fresh soils were passed through a 2 mm sieve, and water was added to obtain a moisture level between 60 and 70 per cent of field capacity. After 2 days of equilibration, 70 g samples were irradiated in a source of Sample containers were cobalt-60 $(6.8 \times 10^5 \text{ rads/h})$. incubated at 25° C, and were never opened before analysis except for leaching tests described later. Exchangeable ammonium- and nitrate-nitrogen were extracted with acidified N-potassium chloride, and the filtrate was analysed. Nitrite was extracted with water at neutral pH, and determined by a modified Griess-Ilosvay technique. All results are means of single determinations on duplicate samples.

The response of nitrogen mineralization in Broad, Icknield and Grove soils 7 days after treatment for the range of doses $5 \times 10^4 - 2.5 \times 10^6$ rads is shown in Fig. 1. In the first two soils nitrite accumulates as soon as nitrate falls with increasing radiation, and two principal mechanisms were considered possible; first, a blockage of the nitrite oxidation process in Nitrobacter spp., or second, the reduction of nitrate.

The rate of nitrite formation in Broad soil was examined by treating 10 g samples at 62 per cent of field capacity with 8×10^5 rads (at 9.0×10^5 rads/h); extractions were made after a series of incubation times up to 128 h after irradiation (Table 1).

Nitrite formed very rapidly, and the instantaneous extraction indicates that it increased during the irradiation period, similarly to nitrate4. Nitrite in the filtered extracts was completely stable up to 5 h at 20° C.

Irradiation of dry, medium and wet Broad soil showed that high soil moisture greatly enhanced nitrite accumulation (Table 2).

To examine whether the accumulated ammonium- or nitrate-nitrogen was the source of nitrite, 10 g samples of

,	Treatment	Moisture % of	Mean p.p.m.	of nitrite-nitrogen day 7	at
		field capacity	Control	8×10 rads	
	Dry	7	2.2	1.2	
	Medium	48	1.4	26.1	
	Wet	8 8	2.0	44.8	

Table 3. ORIGIN OF THE INCREASE IN NITRITE AFTER IRRADIATION

	Mean p.p.m. nitrite-nitrogen 4 h after irradiation			
Leaching solution	Broad soil	Icknield soil		
Water 100 p.p.m. NH ₄ -N 100 p.p.m. NO ₃ -N None	1·4 2·0 9·7 10·1	1·7 0·7 8·9 7·5		

Broad and Icknield soils moistened to 60-70 per cent of field capacity were irradiated in 3.5×10 cm filter tubes with 8 and 6 × 10⁵ rads, respectively. Immediately afterwards they were leached with 100 ml. of water, or ammonium sulphate (100 p.p.m. NH₄-N), or potassium nitrate (100 p.p.m. NO₃-N), all adjusted to pH 7 with 0·1 normal potassium hydroxide. Nitrite was determined after incubation for 4 h (Table 3), and it only appeared in amounts almost identical to irradiated unleached soils after displacement of the soil solution with nitrate.

It was concluded that nitrate reduction was the principal cause of nitrite formation observed in these experiments, and further confirmation with nitrogen-15 will be attempted. It is well known that nitrate is used by micro-organisms instead of oxygen in completely or

partly anaerobic conditions and nitrite accumulates in the medium. Pseudomonas and Bacillus spp. isolated from waterlogged soil have been shown to accumulate large amounts of nitrite in pure culture7.

There are reports of toxicity of nitrite to plants⁸, and because soil sterilized and partly sterilized by radiation is often used or advocated for agricultural research, the growth of lettuce (Lactuca sativa variety 'Cheshunt Early Giant') was examined in pots of Broad soil treated with 8×10^5 rads. A fallowed treatment was analysed during the growing period, and proved the persistence of nitrite after 60 days. Toxicity symptoms8 did not appear, and yields after 60 days of growth exceeded control, as in previous trials with other soils1.

One explanation of nitrite accumulation may be that in some soils there is greater radiation damage to nitrification compared with nitrate reduction, and the latter becomes the dominant process before it, in turn, is inhibited by increasing dose (Fig. 1). Campbell and Lees¹⁰ point out that if aerobic organisms reducing nitrate to nitrite were operative in soil, their activities would be difficult to detect where Nitrobacter is active. Cooper and Smith¹¹ reported nitrite accumulation by nitrate reduction in some alkaline soils, and nitrite reduction was the rate limiting process for denitrification. Allison12 has proposed the formation and decomposition of ammonium nitrite as a mechanism in gaseous nitrogen losses from soil, and it is notable that conditions in the irradiated soils would favour the reaction by ammonia release and partial inhibition of nitrite oxidation.

It is improbable that proliferating organisms are involved in the nitrogen transformations above 5×10^5 rads, but bacterial enzymes are very radioresistant18 and can remain active in non-proliferating cells¹⁴. A residual soil enzyme fraction may even be responsible, of comparable existence to soil phosphatase15.

We thank Dr D. S. Jenkinson for his interest and for valuable discussion.

MICROBIOLOGY

Selective Feeding of Tubificids on Bacteria

THE characteristic abundance of tubificid worms in the benthic coze of sewage outfalls, their curious up-ended posture and sedentary feeding habit suggest a saprobic, non-selective type of nutrition. Feeding has been inter-

preted as a continuous process of indiscriminate ingestion and pumping of an endless column of sapropel through the digestive tract1. We have gathered evidence, however, which does not support this generalization, but indicates selective feeding.

Homogenetes of mixed populations of tubificids (Limnodrilus sp., Tubifex sp. and Peloscolex sp.) were analysed by gas-liquid chromatography for the presence of an organophosphate pesticide (diazinon) incorporated by bacteria on which the worms were fed. It was thus possible to establish, on the basis of diazinon intake, the ingestion of the corresponding bacterium. The bacteria were incubated for 3 days on a mineral salts medium (MSM) which supports a wide range of soil organisms2. Diazinon was substituted for glucose as the carbon source. The cultures labelled with diazinon were then centrifuged and washed three times to remove extraneous diazinon and transferred to aerated cylinders. Each cylinder contained some twenty tubificids previously conditioned for 2 days on 1 per cent sodium substituted MSM with no carbon source. (Tubificids exhibit a marked sensitivity to potassium3.) After 5 days the worms were washed, homogenized in acetonitrile, extracted in petroleum ether and injected into an 'Aerograph' gas chromatograph with an electron capture detector. Diazinon was identified in worms exposed to Escherichia coli, Sphaerotilus natans and Aerobacter aerogenes, but not Arthrobacter sp., Micrococcus flavus and Chromobacterium sp. Behavioural studies had previously indicated no response by the tubificids to the presence of diazinon alone, though the worms readily assimilated the compound.

To determine the nature of the basis for discrimination, the microbial cultures were incubated for 2 days on BHI agar and transferred on 3 in. cubes to 6 in. Petri dishes lined with filter paper and containing § in. of 1 per cent sodium substituted MSM. The response of the worms to different combinations of bacteria was tested by placing three cubes (one control) at equal intervals at the perimeter of the dish and with each respective colony well above the surface of the water (Fig. 1). A 1 in. clump of worms was placed central to, but not touching, each cube. Two forms of avoidance responses were observed: either a clump pulled away by the more distal worms; or when water was too shallow (< 15 in.) to permit the clump response, a streaming behaviour by individual

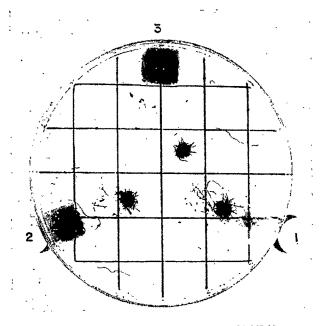

Fig. 1. Avoidance of bacteria by clump migration of tubifield worms.

1. Uninoculated agar control; 2, agar inoculated with Micrococcus flavus; and 3, agar inoculated with Chromobacterium sp.

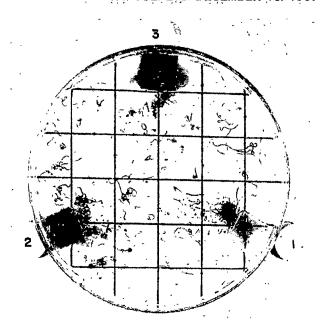

Fig. 2. Avoidance of bacteria by streaming action of tubificid worms.

worms was seen (Fig. 2). Avoidance responses were elicited, in order of decreasing intensity, by Micrococcus flavus, Arthrobacter sp. and Chromobacterium sp. Positive or neutral responses (no avoidance) were demonstrated, in order of decreasing intensity, by S. natans, E. coli, A. Aerogenes and the control. Because avoidance was observed within 0.5 h of initiating the test, the presence of one or more readily diffusible water soluble metabolites is suggested. The identification of the active principle

presently being undertaken.

The results of the chromatographic and behavioural studies agree well. Diazinon was detected in those worms demonstrating a tolerance to the bacteria and not identified where avoidance was elicited. There has been little success in correlating habitat selection with environmental factors^{4,5}. If this laboratory model does reflect field conditions, and food preferences do have relevance in determining population distributions, the resistance of Arthrobacter sp. to ingestion may explain the ubiquity of its distribution: on the other hand, the amenability of E. coli to ingestion may provide a basis for its rapid disappearance from water and soil. In any event, this observation provides a model for further studies in population dynamics.

This work was supported in part by a Public Health Service research grant from the National Communicable Disease Center, Atlanta, Georgia, and by the Office of Water Resources Research.

BOOK REVIEWS

ORIGINS OF THE GENETIC CODE

The Genetic Code

The Molecular Basis for Genetic Expression. (Modern Perspectives in Biology.) By Carl R. Woese. Pp. viii+200. (New York and London: Harper and Row, Publishers, 1967.) n.p.

THE very wide interest in the genetic code which has occurred during the past 6 years stems from the fundamental nature of the relationship of DNA to proteins. The major break-through came in 1961. Then, Nirenberg and Matthaei showed that a codon for the amino-acid phenylalanine was composed of a series of uridylic acid residues, and Crick, Barnett, Brenner and Watts-Tobin showed that the genetic code was a triplet code, and thus a codon for phenylalanine was UUU. Since then the meanings of the sixty-four codons have been elucidated.

Before 1961 much speculative theoretical work, starting with Gamow's diamond code in 1954, laid down the basic ideas of what properties the genetic code might have. These ideas helped in the interpretation of the plethora of experimental results which appeared in the early 1960s. Dr Woese is one of the few people who have devoted much serious thought to the genetic code and it is therefore particularly appropriate that he should have decided to write this book. The first two chapters introduce the reader to the fascinating historical background which the discoveries of 1961 were to obscure so quickly. Chapter 3 covers the experimental determination of which codons code for which amino-acids—the dictionary of the genetic Chapter 4 includes a section on punctuation signals and a thumbnail sketch of control mechanisms, which an uninitiated student might find tough going. The next chapter concludes our knowledge which bears on the genetic code with a standard description of the translation process, including a section on ribosomes, the structure of transfer RNA molecules and Crick's wobble hypothesis.

These first five chapters are all orientated to help the reader consider what the author sees as the next phase in the genetic code: why does the code have the structure it has and, what must necessarily be considered together with this, how did the code and the translation apparatus evolve? This highly speculative field is covered in his two final chapters and it is here that this book distinguishes itself from many others which discuss the more familiar aspects of the genetic code. Basically Dr Woese considers two extreme models of how the code might have "Stochastic" models suppose that the allocation of codons to the twenty amino-acids occurred essentially by a haphazard process and that the order seen in the code today reflects Nature's attempt to minimize the effects of errors made in replication or some step of the translation process. "Mechanistic" models suppose that there was (or is) some structural relationship between a codon and the amino-acid for which it codes, and that therefore phenylalanine was more likely to be coded by UUU than by AAA. Dr Woese tends to favour partly mechanistic models, for he and his collaborators find some correlation between the physical properties of amino-acids and the structure of their codons. The conceptually difficult problem in this field is how a completely selfreplicating unit might have evolved, and what did it contain. Are transfer RNA molecules very primitive structures? Are they as large as they are because the most primitive translating system had no ribosomal

structure and the adaptors had to be big enough to "stick" to one another?

This book presents a particularly personal approach to the genetic code as seen by a theoretician. This has its merits in that the reader is unlikely to lose his path in a maze of biochemistry. It is unfortunate, however, that an excess of new jargon has appeared (such as "AERSs" for the activating enzyme recognition sites of transfer RNA molecules), that most molecules have become "tapes" or "tape-readers" and that several needless and trivial errors occur (the structure of uridylic acid in Table 1-2 has a gratuitous "+CO₂"). In parts the style is over-dramatized, but apart from these criticisms this book is a stimulating and valuable contribution to those wishing to understand how the code was solved and what its solution means in terms of the origins of life.

MARK S. BRETSCHER

LAKE DISTRICT LANDSCAPES

A History of Man in the Lake District By William Rollinson. Pp. xii + 162 + 15 plates. (London: J. M. Dent and Sons, Ltd., 1967.) 42s. net.

FEW regions in the British Isles have been as fortunate as the English Lake District in the quality of the descriptive writings they have inspired. Thomas West wrote his Guide in 1778 and William Wordsworth wrote in 1810. The poet envisaged the area "as a sort of national property" and since 1951 its 900 square miles have been one of Britain's most popular National Parks. It was here, too. that the National Trust had its home and became possessed of its first property in 1902. Scientific survey, however. has not kept pace with romantic conservancy, although W. G. Collingwood showed the way in 1925. Since then many geological, ecological and economic studies have been made, but no comprehensive survey of the evolution of the cultural landscape has appeared. This book partly fills the gap, though it is aimed at the interested layman and makes no claim to be a work of detailed scholarship. The author's statement that the fascination of the post-Roman period lies in the fact that there can be few certainties about it clearly puts him on the side of the romantics rather than the scientists.

The approach is systematic, but the first chapters on geology, glaciology and archaeology are sketchy and uncritical and the information often out of date. The interest of the writer, and therefore of the reader, quickens as the historic periods are reached, and the best sections are those dealing with agricultural and industrial development. The final chapter is a reasoned statement of the problems of combining conservation with maximum use of the region's resources. The photographs and the line drawings are attractive, in particular the distribution maps, but scientific accuracy is sacrificed by the use of picture symbols which may occupy more than a square mile of ground. The book is marred by innumerable disrupting footnotes which should have been incorporated in the text, and has other marks of the beginner. The author is clearly deeply attached to the Lake District and knows it well, yet the full flavour of field work is missing. Having cut his teeth on the area, he should go on to bite E. E. EVANS deeper into it.

DEVELOPING TRADE

The Growth of the British Cotton Trade 1780-1815. By Michael M. Edwards. Pp. viii+276. (Manchester: Manchester University Press, 1967.) 45s.

THE British cotton industry was the first major industry to be completely mechanized and converted to the factory system: it has been termed the "leading industry" in the first Industrial Revolution. It has fascinated many observers, and a small library has been written about it. Yet, surprisingly, numerous gaps in our knowledge about it remain to be filled, and this volume fills one of them with great skill and perspicacity. The author, in fact, treats his topic with remarkable mastery and maturity, and only the unnecessary length and detail of the book betray its origin as a doctoral thesis.

The period chosen is dominated by the war against France, and it is useful to be reminded how much the major wars of the period up to 1815 did influence the course of British industrialization. The author, with his detailed, almost microscopic knowledge of the period, discerns the alternation of years of heavy investment and expansion, 1780–1792 and 1798–1803, and years of over-production, loss of markets and stagnation, 1793–1797, and summer 1803–1815. Although the case for writing off the whole of that last period is not altogether convincing and is contradicted by some of the evidence, the division is useful, and it is salutary for our understanding of the age to be made aware that high profits, even in cotton spinning, were not automatic and not continuous.

There are two main themes covered by this study. One is the organization of the trade, the merchants. brokers, commission agents and factors who imported and distributed the raw cotton, the yarn and the finished cloth; the other is the method of financing specialization and skill, with the growth in the size of the industry in those years; and both show the remarkable flexibility and inventiveness of the age in organizing its buying, selling and financing. The extent to which the industry bent financial institutions to meet its needs is again confirmed, and so is the relative unimportance of fixed capital, and the weight of circulating capital, like work in progress and mutual indebtedness, in which the banks, despite the conventional picture of aloofness from industrial entanglements, played a principal part. Although there were, as there always have been, price fixing agreements by the big units, there was no monopoly and the environment was basically highly competitive. In these conditions the drive for more cotton and for more money was like a flood, breaking down its obstacles or, where it could not entirely sweep them away, seeping through the cracks, swirling around the blockages and undermining the opposition. In the end, nothing could hold up the use of the new power.

It is, perhaps, a pity that economic science took this mobile, flexible, inventive and competitive world as its model, holding other conditions to be deviations or falls from grace. The conditions in the cotton industry in its first generation of the factory system were exceptional, perhaps even unique. It was probably the only period in history where all the initiative came from below, where ability was more important than money in the rise of the individual, and where greed and ruthlessness became a force which imparted a mighty turn to the wheels of human progress.

FRAMEWORK OF GEOLOGICAL DATA

The Stratigraphy of the British Isles
By Dorothy H. Rayner. Pp. x+453+8 plates. (London: Cambridge University Press, 1967.) 70s. net; \$12.50.

This is a welcome and, by any standards, remarkable book. Dr Rayner, senior lecturer in geology in the University of Leeds, has made a synthesis, broad but well founded in details, of the succession and occurrence of rocks in the British Isles. Ireland is at long last accorded its rightful place in the scheme of things. Such a synthesis, which has not appeared for several decades, will be seized on by famished college and university teachers for use in their more advanced courses. The British Isles are

geologically highly complex, and the literature on the succession of deposits must run into tens of thousands of items, controversial issues abounding. Though rarely demonstrated explicitly in the text, Dr Rayner has clearly brought herself to master the detail as well as the essence of these various publications, a selection of which is listed. Works dated 1967 are included in the book and there are footnotes dealing with some very recent discoveries. The assimilation of all this information has in no way detracted from Dr Rayner's clear and unobtrusive style of writing.

The author's method is simple. The geological systems are treated chronologically, one to a chapter, except for the Ordovician and Silurian which are treated together in one, and the Carboniferous which is split between two. Each chapter begins with a general statement which includes a list of the principal divisions of the system together with a map of present outcrops and the chief physiographic elements of the time. There follows an expansion of this in terms of either geographical regions or geological units, as the circumstances of outcrop and knowledge dictate. There is usually a terminal summary in which difficulties are high-lighted. Two chapters are not concerned with a system. The first chapter, intended to remind the student of what he has learned elsewhere, is a review of stratigraphical concepts and methods, and a general account of the tectonic setting of the British Isles. The final chapter, called an epilogue, reviews briefly the kinds of data on which palaeogeographies have recently been based; some attention is given to the hypothesis of continental drift as affecting the North Atlantic border-

The Pre-Cambrian rocks of Britain are highly complex, for they exist in scattered outcrops greatly diversified as to scale and succession. The principal exposures, in Scotland, are associated still with major controversies. Dr Rayner's view is that the Moine rocks are probably equivalent to the Torridonian. Unfortunately, the section on the Torridonian itself already needs modification in the light of recent work which has demonstrated the existence of an unconformity and large time-gap within the series.

Wisely, the author groups the Dalradian rocks of Scotland and Northern Ireland with beds elsewhere classified as Cambrian. The implications of drift are accepted and the scene is set for the protracted events of Lower and early-Upper Palaeozoic time. The British Isles are seen as definitely peripheral, in Cambrian times, to the North American shield; a structurally stable area is glimpsed in north-west Scotland, and to the south-west of this lie the Ecoambrian Dalradian trough and somewhat younger basins of Wales and Ireland.

The Ordovician and Silurian rocks of Ireland are, generally speaking, poorly known compared with the mainland successions. However this may be, the integration of data from the two islands leads to a convincing picture of the distribution and character of the several basins and swells distinguishable in the beds. The pattern of distribution could, however, have been demonstrated more clearly if more attention had been given to maps of sedimentary facies and sediment dispersal. Data of these kinds are central to a grasp of the roles played by the different structural units.

In the British Isles the Devonian is represented by rocks chiefly of the Old Red Sandstone facies. These beds straddle in time a major tectonic event, for the Lower Old Red Sandstone is essentially "Lower Palaeozoic" in distribution and relationships, while the Upper Old Red Sandstone broadly exemplifies Upper Palaeozoic patterns. It is in this chapter on the Devonian that one particularly misses in Dr Rayner's treatment the link between sedimentation and tectonics. Her account of the succession of rocks is exemplary, but what may lie concealed in the unconformities discussed receives scarcely a mention. These hidden events are not altogether speculative, however. On a minor point, one cannot agree with Dr Rayner over

her interpretation of the Middle Old Red Sandstone break in Ireland, or with her over-simplified account of Upper Devonian events in South Wales.

No system in the British Isles has been so intensively studied as the Carboniferous, and the account of this is a model of concision. Comment is required only on minor points. The author should have made it clear that some of the Namurian Grits of the Pennine area have been derived from the south, off St. Georges Land. The relationship of the succession in the South Wales Coalfield to the Culm of Devon and Cornwall is not clarified. The knowledge that a part of the Coalfield succession is of southerly origin should have invited a closer analysis.

In Germany and the Netherlands there are Permian and Triassic standards of great importance to an understanding of the British succession. Dr Rayner refers to these standards, but is hampered in her application of them to Britain by the difficulties of dating the British rocks. The depositional break at the base of the British Keuper is mentioned but is accorded no particular significance. It now seems likely, from palynological and other work done on the mainland and in connexion with North Sea exploration, that the Keuper Sandstone is of late Bunter age. The whole early "Keuper" sequence may reveal in Britain events closely connected in Germany and the Netherlands with the Muschelkalk transgression. Other kinds of environment seem preferable to Dr Rayner's Keuper "plains and lakes".

We find the author on firmer ground when it comes to the Jurassic, Cretaceous and Cainozoic rocks, all of which have been much studied. The account of the Jurassic System is unexceptionable and mercifully brief. Only one comment is due as regards the Cretaceous. Dr Rayner assigns the final submergence of the London Platform to Gault times; the sedimentological evidence, however, points to a connexion by at the latest the end of the Lower Albian. A stronger exception must be taken to the interpretation placed on the Reading Beds which begin the Cainozoic in the area west of London. At least the basal gravel of this formation is fully marine, and there is evidence that the higher rocks may be of littoral origin. The Palaeocene transgression was probably as widespread as the later, though more substantial, Ypresian one.

Too often the British geologist dismisses Plio-Pleistocene deposits as a subject of little concern. This is an unfortunate view, for herein is to be found a greater range of geological phenomena than in perhaps any older beds. Moreover, the late Pleistocene deposits afford a natural laboratory in which process and geological resultant can be closely matched. The task of outlining the Plio-Pleistocene of Britain has not been shirked, but the complexity of the subject finally defeats Dr Rayner. Once the Crags have been dealt with, the treatment falls below the high standard set in earlier chapters.

It would be ungracious to deny Dr Rayner the praise due to an important work, yet false to suppose that other interpretations of the subject of stratigraphy did not exist. It is fair to conclude that Dr Rayner aligns herself perhaps more with the "classical" than with some modern conceptions of the subject. This viewpoint invites a number of questions which all geologists should debate with themselves from time to time. Can there be a stratigraphy of the British Isles, or is this yet another conceit of the island race? What of the geological units—especially the Caledonides and Hercynides—of which the British Isles once formed a part? Should a stratigraphy be developed for these units rather than geographical or political ones? What place should be given to the relationship between sedimentation and tectonics? If the connexion is recognized—and this seems unavoidable—then unconformities should be explored in as much detail as sedimentary formations. Further, isopachous, facies and sedimentdispersal maps would have an important place in any stratigraphical account. Can a rehearsal of outcrop, zone and lithology be considered enough? J. R. L. ALLEN

ATTRACTION OF EARTH

The Gravity Field of the Earth from Classical and Modern Methods

(International Geophysics Series, Vol. 10.) By Michele Caputo. Pp. xiv+202. (New York: Academic Press. Inc.; London: Academic Press, Inc. (London). Ltd., 1967.) 78s.

In this book Dr Caputo provides a useful exposition of the framework of mathematical theory needed in studies of terrestrial gravity and the external gravitational field. The theory expounded in the first part of the book is applicable mainly to measurements made on the Earth's surface, by the traditional methods of gravity survey and geometrical geodesy. The theory is developed in terms of ellipsoidal co-ordinates, and gives in closed form the potential of a rotating planet whose gravity field has an ellipsoid of revolution as an equipotential surface. The practical problems to which the theory applies include the international gravity formula and hydrostatic equilibrium figures. In the remaining seventy pages of the book the theory of Earth satellite orbits is developed. generally on quite conventional lines, by expanding the gravitational potential in Legendre polynomials. section ends with a review of recent determinations of the geoid by analysis of satellite observations.

The book is written in a pleasant style and the virtues of the "ellipsoidal approach" are well brought out. Certainly this approach has advantages, but it also has deficiencies, as the author tacitly admits by not adopting it when he comes to treat satellites. The book is well produced, and expensive; misprints are fairly frequent, but usually trivial.

MODELS IN STRUCTURAL GEOLOGY

Gravity, Deformation and the Earth's Crust As Studied by Centrifuged Models. By Hans Ramberg. Pp. ix+214. (London: Academic Press, Inc. (London). Ltd.; New York: Academic Press, Inc., 1967.) 57s. 6d.: \$11.

THE use of scale models to investigate the mechanical processes in the Earth's crust has had limited success. This is because of the well known difficulty of scaling down the dimensions, the time scale, the forces and the mechanical properties in the same model. One of the greatest hindrances has been the lack of a sufficiently large body force in the model to represent gravity. This has been a serious difficulty, for gravity has a profound influence on the formation of most geological structures and it is the controlling factor in some of them.

Ramberg has made an important contribution to structural geology by introducing the centrifuge technique into scale model investigations. This enables centrifugal accelerations of up to 3,000g to be applied, which can provide at last a realistic representation of gravitational body forces in the crust. The central theme of the book is the application of this technique to problems such as the rise of salt domes (so important in the North Sea oil hunt) and the uplift of mountain ranges. Some noncentrifuged models are also included, and the experimental work is backed up by theoretical calculations which are mainly based on Newtonian viscosity.

The book contains much important information for the structural geologist. One can mention the demonstration by theory and experiment that the downbuckling mechanism of geosyncline subsidence cannot work, and the beautiful scale model experiments of salt dome rise. There is also controversial matter, such as Ramberg's preference for vertical body forces to horizontal compression as the primary mechanism for mountain building.

Professor Ramberg is to be congratulated on his important contribution to geology. The same cannot be said. however, for the production of the book. It makes slow and often uninteresting reading despite the exciting subject matter. Perhaps someone ought to read the article by the Editor of *Nature*, "Is the Literature Dead or Alive?"

M. H. P. Bott

QUANTUM MECHANICS

The Mathematical Principles of Quantum Mechanics By Derek F. Lawden. Pp. xiv + 280. (London: Methuen and Co., Ltd., 1967.) 50s. net.

DURING the past twenty years or so, a scarcity of books on quantum mechanics has been happily transformed into a situation where there now exists an embarrassingly wide selection of good books on this fundamental subject, so that the need for new books has considerably diminished unless they possess some original feature.

As its title suggests, the volume under review sets out to emphasize the mathematical aspects of quantum mechanics while mostly disregarding the physics of the subject. The book begins with a chapter on the representation of states by vectors in a multi-dimensional vector space. Then comes a chapter on spin operators followed by chapters on operators possessing continuous eigenvalue spectra, on the variation of state vectors with time, on angular momentum operators, on perturbation theory and on Dirac's relativistic theory of the electron.

The presentation of the subject matter is quite straightforward. The operator approach to quantum mechanics is chosen as the basis of the subject and the Schrödinger equation arises in the development as the eigenvalue equation for the Hamiltonian operator in the co-ordinate representation. Regrettably there is virtually no discussion of the relationship between the Schrödinger equation and classical mechanics: my belief is that this connexion is an extremely important one, for it leads to considerable clarification of the position of quantum mechanics in the general field of physics, and indeed was the original approach used by Schrödinger.

This book by Lawson also omits discussion of variational principles and methods, and it only takes a cursory glance at the theory of collisions as an application of perturbation theory. Nevertheless it can be recommended to a student whose primary interest is in the mathematical aspects of quantum mechanics, for it presents a lot of valuable material very clearly, but for a fuller understanding of the subject it would need to be supplemented by other books.

B. L. Moiseiwitsch

NEW ASPECTS OF REPRODUCTION

Advances in Reproductive Physiology

Vol. 2. Edited by Anne McLaren. Pp. 347. (London: Logos Press, Ltd., in association with Elek Books, Ltd., 1967. Distributed by Academic Press, New York and London.) 75s.

It can be argued with some justification that there are already too many books on fertility and reproduction. Certainly, there is a wealth of review on the subject and it is depressing, not to say painful, to compare the volume of relevant literature with its substance. As a discipline, the biology of reproduction seems to be sorely in need of a major breakthrough, and a constant flow of monographs, in which authors repeatedly ask the same questions instead of getting on with answering them and saying something new, can be extremely tedious. Moreover, there is always the danger that the "multiple author" type of book merely serves as a platform for certain individuals to parade as experts in their field. A book intended to be purposeful can thus be marred. Such judgments should, of course, be tempered by the fact

that monographs involve an enormous amount of difficult work, and if they are done properly they should be and are of interest and great value.

Anne McLaren clearly has a flair for editing, for she avoids almost all the best known pitfalls. It is claimed in the editor's foreword that the volume is "...neither balanced or integrated", and it would seem largely because of this that the book is by no means a run of the mill text on reproduction.

The first two chapters are about behaviour. This alone makes the book "different" and is an advance on volume 1 which covered more conventional topics. The first chapter of volume 2, by Margaret Bastock, is particularly effective in that it contains a nice attempt to integrate behaviour and physiological mechanisms, and although in the second chapter M. P. M. Richards does not try to do this, he succeeds in making maternal behaviour in rodents and lagomorphs a fascinating subject.

A. B. Gilbert writes the third chapter on egg formation in the chicken. This is a novel and absorbing part of the book and its inclusion is most refreshing. Lightheartedly, however, I cannot resist mention of the banality of the opening sentence in this chapter which is only outshone by the opening phrase of the next chapter. Chapter 4 is written by B. J. Restall and is an attempt to survey the biochemical and physiological relationships between the gametes and the female reproductive tract. To try to do this in twenty pages is to attempt the impossible and, needless to say, the impossible has not been achieved. Nevertheless, the twelve pages of references are a useful supplement to a brave if superficial approach to the problem.

Chapters 5 and 6, respectively, on oestrogens and implantation, are erudite, but less appropriate to this volume than most of the other chapters. This in no way reflects on such distinguished authors as Professors Emmens and Psychoyos; indeed, chapter 5 is probably the best written chapter in the whole book. But the subjects are too topical to be in context. Could it also be that in these two chapters much is assumed for the uninitiated, and little new is added for the expert? It will be for each sort of reader to make a personal decision on this.

A chapter by Peter Gruenwald on growth in the human feetus is a valuable contribution, and the closing chapter by J. M. Tanner on puberty is scholarly and affords some intriguing information, even though it is perhaps a bit light on purely physiological aspects of the problem.

This book should have wide appeal, and it can certainly be recommended to reproductive physiologists and other biologists, not because it is just another book on reproduction, but because it is an unusual and informative book on reproduction. The title of the book bears hardly any relation to its contents, but this is of little import here, and if anything it enhances the interest.

T. D. GLOVER

Appointments

REAR-ADMIRAL F. Dossor has been appointed director of hovercraft at the Ministry of Technology.

DR R. B. BUZZARD, at present research director of the National Institute of Industrial Psychology, has been appointed director of the institute in succession to Dr C. B. Frisby.

Announcements

C. H. Van de Hulst, professor of theoretical astronomy at Leiden, has been elected to succeed Dr A. Hocker as chairman of the council of ESRO for 1968; Professor R. Lüst, director of the Max-Planck-Institut für Extraterrestrische Forschung, Munich, and chairman of the Launching Programmes Advisory Committee of ESRO, and Dr J. Stiernstedt, head of the Department of

the Royal Ministry of Education and chairman of the Swedish Committee for ESRO, have been elected vice-chairmen.

PROFESSOR IGOR TAMM, of the Rockefeller University, has been awarded the Alfred Benzon Prize for 1967 for his achievements in virus research. The award was made in Copenhagen and Dr Tamm became the first American to receive the award of \$3,600 and to deliver the Alfred Benzon Lecture.

ERRATUM. In the News and Views note "Royal Society Blooming" (Nature, 216, 841; 1967), the study group under the chairmanship of Dr H. A. Cole should be described as being concerned with marine pollution.

CORRESPONDENCE

The Brain Drain

SIR,—The emigration from Britain of trained scientists and engineers is a matter on which expatriate Britons also reflect. I came to the United States 15 years ago, before the brain drain became fashionable, and have observed the drain mainly from the American end, though I have kept in touch with the situation at home through my annual visits to Britain. Because my experience has lain principally in British and American universities, I am better acquainted with the flow of scientists and engineers from and to these institutions than I am with conditions in industry. But I assume that a reversal of the brain drain in the educational and research fields would not be frowned on in Britain.

It is of advantage to Britain that its young scientists and engineers should spend two or three years in a new environment learning new methods. The only real problem is to get them back again after they have spent some time in North America.

The British Government's Working Group on Migration and the leading article in Nature of October 14, 1967, wish to attribute the brain drain mainly to the higher dollar salaries current in North America. This idea must be based on arithmetic alone: £5,000 converted at 2.8 yields \$14,000 (\$12,000 since November 18) and therefore \$14,000 presumably enables a man and his family to live in North America in the way he could live in Britain if he earned £5,000. An illusion such as this can only be dispelled by living for a time on this side of the Atlantic as an ordinary resident and not as a much-fêted temporary Before I came to the United States I was a department head in the University of London and I am now one in my present post. On our visits to Britain, my wife and I have noticed that our friends who are department heads and their families live precisely the kind of lives which we would choose to live were we back at home, and which we do live in the United States as far as circumstances permit. Our friends have pleasant houses, they own cars, they travel in Europe for their holidays, they send their children to schools of their choice, and so on. Yet the salaries of these men, multiplied by 2.8, let alone by 2.4, yield sums in dollars that seem pathetically small compared with my salary at the University of Illinois. The arithmetic, however, takes no account of the inescapable circumstances of North American life such as the rigorous climate or the sheer size of the country, to name but two. To keep warm in the bitter cold of winter and cool in the suffocating heat of summer is costly; the relatively thin spread of the population over this vast continent means heavy expenditures on transportation. Undoubtedly a scientist or engineer, whether he works in the United States or Britain, would like to have, and deserves, a good salary. He does not want to see his family in straitened circumstances. But what constitutes a good salary in either country is not merely a matter of arithmetic and of cost of living indices. It is most easily arrived at by living in each country in turn and is largely conditioned by the individual's idea of the kind of life he and his family want to live.

The Working Group on Migration is quoted in the New York Times of October 11 as stating that "the brain drain is essentially a consequence of a national attitude [in Britain]". This appears to me to be a far more pertinent remark than the pre-occupation with salaries converted from pounds to dollars at the official rate. Too often, as the British scene is viewed from a distance, the conclusion is reached that a man there regards his work as a boring nuisance which is to be got through with the least effort on his part and in any slipshod fashion. Against this, a man's income is sacrosanct and is owed to him by society irrespective of the quality of his work. Some years ago, in a large Glasgow factory, two or three workers were dismissed for slovenly work. All the workers in the factory immediately went on strike: in their minds apparently performance and wages were unconnected. attitude is the antithesis of that of the scientist and, I believe, of the engineer as well. They would not be what they are if they did not regard their occupations as absorbingly interesting in themselves and if they were not striving to do the best job they could. Moreover, they need the help of technicians if they are to operate successfully. If the technicians were to adopt the attitude of the Glasgow factory workers, scientists and engineers would have to look forward to much time spent in a state of frustration.

It is also sometimes said that the brain drain is partly caused by the emphasis in Britain on "hierarchy and status". But this is no more than a minor irritant. The veneration accorded in Britain to membership in the Royal Society certainly looks faintly ridiculous from this side of the Atlantic. Over here, as far as I can judge, it is recognized that scientific genius is not the only passport to entry into academies like the US National Academy of Sciences or the British Royal Society.

Neither salaries nor these British attitudes are insuperable obstacles. Every society, the American included. has its disadvantages, and scientists and engineers are sufficiently intelligent people to realize this. As is reported in The Observer of October 15, it did not take Mr Philip Burnford, of Management Selection International, long to discover, after he had set up his office in New York. that many expatriate scientists and engineers wanted to go back to Britain if they could find out how to do it. But, apart from the question of method, I think that many of them doubt that they are wanted back at all. Most scientists are made to feel that their work has some value when colleagues in other institutions ask them to visit and lecture on the matters on which they are engaged. During the 15 years that I have been here I have often been asked to lecture at other institutions in this continent. I have also been invited to speak more than once at institutions in Germany, France and Portugal, countries that are not markedly richer than Britain. Yet it is only this year that, for the first time, an invitation of this kind has come from Britain. Hitherto, I had supposed that the work I was doing was of no interest to British scientists. An important result of my visits to Britain this year has been that I have been able to see the quite remarkable facilities available in a number of British universities. I am now able to encourage young expatriates to return in a way that was impossible to me before. Those scientists who remain in Britain know what the expatriates are doing because scientists at home presumably read the technical American scientific journals. Graduate associations also keep addresses of expatriates and can say where a man is located. A little money must be spent if expatriates are to be invited to address their colleagues in Britain. But the cost is not as large as might be thought, because the trip across the Atlantic may well be combined

with one financed by the expatriate's US institution, for some other purpose, or because he, in any case, has to return for some family reason. Even an invitation to give a lecture, which cannot be accepted for financial reasons, would serve to encourage an eventual return home. It does at least indicate to the expatriate that he has not been written off as dead.

I have had some indications that expatriates who wished to return have sometimes felt that they had received a somewhat cold reception from the British interviewing authorities in Washington. It is, of course, true that the Joint Interviewing Board, contrary to popular mythology, does not have the reversal of the brain drain as its primary function. Two students of mine returned a few years ago from one of these interviews in a very despondent frame of mind because they thought they had been confronted by a take it or leave it attitude. Their comments were not as caustic and unflattering as those of eight returned brain drainees, now working for Imperial Chemical Industries, which are quoted in an article by Kay Evans in The Observer of October 22. Had there not been an overriding reason which made a return to Britain imperative, my students might well have stayed in the United States or Canada and might have refused the job eventually offered them by the JIB. I believe that efforts are being made to remedy this situation. I have before me an advertisement in an American scientific journal issued by the British recruiting authorities in Washington and Ottawa. It is informative and business-like, but again I miss any sign of enthusiasm for the recovery of the lost sheep. The expatriate must regard nimsen only as a "candidate" for a post at home. He may well ask himself The expatriate must regard himself only as a why he should trouble to do so if the Americans are asking him to stay on with them. The advertisement may well attract a response only from those who have found themselves to be misfits over here.

My proposal to those at home, if they want to reverse the brain drain, is: Show an interest in the expatriate scientist or engineer, tell him that he would be welcomed back and ask him to return! You may well be surprised at the response you will receive. This conclusion I had reached some years ago. I was delighted to see, again in the October 22 article in *The Observer*, that Imperial Chemical Industries had been successfully practising the method for some time.

Organization at Ministry of Technology

SIR,—Your issue of November 25 reported a speech by Sir Richard Clarke, Permanent Secretary, Ministry of Technology, to a joint meeting of the Royal Institute of Public Administration and the British Institute of Management (Nature, 216, 745; 1967). Sir Richard compared the chances of able administrators, engineers, scientists and other specialists, getting to the top posts in his ministry relatively young, and concluded that the prospects were probably the same on all ladders. This is a seriously misleading statement. The fact is that in the Ministry of Technology able engineers and scientists have markedly inferior prospects to those of administrators of getting to the top. In this respect, this ministry is no different from the rest of the Civil Service.

There are 150 administrators in the Ministry of Technology of whom 22 are on salaries of £5,000 or more, that is 14.7 per cent. There are 1,985 scientific officers of whom 40 are on salaries at this level, that is 2.02 per cent. The prospects for professional engineers are much worse; there are about 1,100 qualified professional engineers of whom only 3 are at this salary level, which is much less than 1 per cent.

For the Civil Service as a whole, the comparative percentages of those on £5,000 or more are: administrators; 15·3 per cent; scientists, 2·3 per cent; professional engineers, 0·2 per cent.

The explanation is simple. At the highest levels in the Civil Service, and in spite of the changing role of government, management and administration are still almost exclusively the monopoly of the administrative class. Although departments differ in size, function and complexity, one thing remains constant: an administrative Permanent Secretary is at the head and he has one or more deputy secretaries, according to the size of the department, and a varying number of under secretaries, all of whom are members of the lay administrative class. Out of 36 posts at Permanent Secretary level, 33 are filled by members of the administrative class. This class is relatively small and consequently the career pattern referred to above is produced. As long as advice to Ministers, policy determination, and the control of the governmental machine are vested in the administrative class, the opportunities of advancement for scientists and engineers to the very top posts will be seriously restricted.

The Jones Committee on the brain drain said that last year Britain suffered a net loss of 1,870 engineers and technologists, aged chiefly between 25 and 35, which is a third of our average annual output, and that the trend was increasing. It forecast disastrous consequences for British industry and the economy within ten to twenty years if it were to continue at the present rate.

The Prime Minister has laid the chief blame on the British industrial system, which, he has said, did not put a proper valuation on such people. The Treasury has overall responsibility for career management in the Civil Service, but, in spite of all that has been said by its political masters about the need to improve both the status and the responsibilities of engineers and scientists, it regards comparisons between administrators on the one hand and professional engineers and scientists on the other as having neither validity nor relevance. Institution has tried repeatedly to persuade the Civil Service to remedy this situation but without avail. Statements and pledges have been made by various Governments from time to time which indicate, in the clearest possible way, the need for major reform. clearest pledge on the question of parity as between the administrative and the professional civil servant was given by Lord Cherwell, speaking in the House of Lords on behalf of the Government, as far back as 1943. He said: "I must frankly admit that the Civil Service has not hitherto shown due regard for the contribution which scientists are making to the nation's welfare. I am glad to be able to say in answer to Lord McGowan's question that this matter has now been reviewed, and that an investigation has been in progress to make sure that the conditions of service, pay and prospects of Government scientific employees compare favourably with those on the administrative side of Government work, so that, among other things, interchange may in suitable cases be made easier. I hope that a definite announcement that these reforms are to be put into effect may be made before long." There is great rigidity in the nineteenth century class "caste" system in the Civil Service, which cannot be modernized to fit purposive government without causing trouble. I leave it to your readers to judge for themselves the extent to which the Civil Service has implemented the long outstanding Government pledge which Î have quoted.

Yours faithfully,

T. H. Profitt Deputy General Secretary.

The Institution of Professional Civil Servants, Northumberland Street, London, WC2. Ţ.,

FORTHCOMING EVENTS

(Meetings marked with an asterisk are open to the public)

Monday, December 18

SOCIETY OF CHEMICAL INDUSTRY, PESTICIDES GROUP (at 14 Belgrave Square, London, SW1), at 3.30 p.m.—Meeting on "New Insecticides and Fungicides".

Institution of Electrical Engineers (at Savoy Place, London, WC2), at 5.30 p.m.—Discussion Meeting on "Cabling for Difficult Industrial Environments", opened by Mr G. L. Leighton, Mr D. Balk, Mr D. J. Mills and Mr T. B. Rolls.

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2), at 5.30 p.m.—Discussion Meeting on "Recent Developments of Inductive Radio Standards", opened by Mr J. J. Hill.

Tuesday, December 19

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, London, WC2) at 5.30 p.m.—Dr F. E. Jones: "The Management of Men and Money in an Electronics Company".

INSTITUTION OF MECHANICAL ENGINEERS, RAILWAY ENGINEERING GROUP (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p.m.—Discussion Meeting on "Kitchen Car Equipment".

Wednesday, December 20

INSTITUTE OF NAVIGATION (at the Royal Institution of Naval Architects, 10 Upper Belgrave Street, London, SW1), at 2.15 p.m.—Mr A. P. W. Cane, Mr J. W. Blanchard and Captain F. Ormonroyd: "Instrument Approach Criteria".

ROYAL SOCIETY OF MEDICINE, HISTORY OF MEDICINE SECTION (at 1 Wimpole Street, London, W1), at 5.15 p.m.—Dr T. D. Whittet: "Pepperers, Spicers and Grocers, Forerunners of the Apothecaries".

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, SW1), at 6 p.m.—Mr J. W. Belth: "Selling of Engineering Producta" (Thomas Hawksley Lecture).

Thursday, December 21

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W1), at 4 p.m.—Scientific Papers.

LONDON MATHEMATICAL SOCIETY (at the Royal Astronomical Society, surlington House, Piccadilly, London, W1), at 5 p.m.—Professor J. R. ingrose: "Derivations and Automorphisms of Operator Algebras".

APPOINTMENTS VACANT

APPLICATIONS are invited for the following appointments on or before the

APPLICATIONS are invited for the following appointments on or before the dates mentioned:

HEAD (physicist with an established reputation of elementary particle physics research) of the Bubble Chamber Research Group, to be responsible both for the research programme of this group and also for the collaboration with all the University Bubble Chamber Groups who use NIMROD—The Director, Rutherford High Energy Laboratory, Chilton, Didcot, Berkshire (December 22),

LECTURERS (2) in the DEPARTMENT OF CHEMICAL ENGINEERING—The Registrar, University College of Swansea, Singleton Park, Swansea, South Wales (December 23).

LECTURER IN DENTAL BIOCHEMISTRY—The Secretary of the University Court. The University, Glasgow (December 29).

DEMONSTRATOR In the DEPARTMENT OF GEOGRAPHY, to demonstrate in map laboratories and to engage in tutorial and field work—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (December 30).

map laboratories and to engage in tutorial and field work—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (December 30).

LECTURER and an ASSISTANT LECTURER IN PHYSICAL CHEMISTRY—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W8 (December 30).

LECTURER (with a special interest in the application of quantitative techniques to regionalism, or urban studies or land use) in the DEPARTMENT OF GEOGRAPHY—The Secretary, University of Edinburgh, Old College, South Bridge, Edinburgh (December 30).

LECTURER IN ENGINEERING MATHEMATICS—The Registrar, The University, Newcastle upon Tyne (December 31).

SENIOR RESEARCH ASSISTANT (with an honours degree, preferably the chemistry) to assist Professor N. Shappard with the research work of his group in the School of Chemical Sciences, and duties will include work in connexion with research grants and publications, literature and surveys and reviews, and liaison with individual research workers—Dean of the School of Chemical Sciences, University of East Anglia, University Plain, Norwich, NOR 85C (January 1).

PROFESSOR OF ZOOLOGY in the DEPARTMENT OF BIOLOGICAL SCIENCES, University of the West Indies, Trinidad—The Inter-University Council, 33 Bedford Place, London, WCI (January 4).

HEAD OF THE DEPARTMENT OF PHARMOV—The Principal, College of Technology, Belfast, Northern Ireland (January 5).

LECTURER IN ENGINEERING MATHEMATICS—The Secretary, The Queen's University, Belfast, Northern Ireland (January 5).

PROFESSOR OF BIOCHEMISTRY in the FAULLTY OF MEDICINE, University of the West Indies, Jamaica—The Inter-University Council, 33 Bedford Place, London, WCI (January 10).

LECTURER (SENIOR LECTURER in PHYSICS at the University of Queensland, Australia—The Association of Commonwealth University of Queensland, Australia—The Association of Commonwealth University of Sydney, Australia, Chair of Chemical Engineering at the University of Sydney, Australia

CHAIR OF CHEMICAL ENGINEERING at the University of Sydney, Australia
—The Secretary-General, Association of Commonwealth Universities (Branch
Office), Marlborough House, Pall Mall, London, SW1 (Australia and London,

fanuary 31).
OFFICIAL FELLOW OF LECTURER IN ORGANIC CHEMISTRY—The Secretary,

Solliof College, Oxford (February 1).
UNIVERSITY NUCLEAR PHYSICS RESEARCH FELLOWS (with a Ph.D. and a pecial aptitude for research in high or low energy nuclear physics)—The legistrar, The University, Liverpool, quoting Ref. RV/286/N (March 1).

Animal Technician for the College Animal House—Mr L. Foster, Chelsea College of Science and Technology, Animal House, Manresa Road, London,

ASSISTANT CYTOLOGIST (science graduate, preferably with experience in human chromosome cytology and cell culture) in the HUMAN CYTOGENETIOS LABORATORY—The Group Medical Superintendent, Royal Hospital for Sick Children, Court

human chromosome cytology and cell culture) in the HUMAN CYTOGENETICS LABORATORY—The Group Medical Superintendent, Royal Hospital for Sick Children, Glasgow, C4.

ASSISTANT EXPERIMENTAL OFFICER (with qualifications in physics or metallurgy or electrical engineering) for the ELECTRON MICROSCOPE LABORATORY—Head of Chemical Engineering and Chemical Technology, Imperial College of Science and Technology, London, SW7.

POSTDOOTORAL BIOCHEMIST (preferably with experience in protein and nucleic acid biochemistry) in the DEPARTMENT OF IMMUNOLOGY to investigate mechanisms of cellular hypersensitivity—The Secretary, St. Mary's Hospital Medical School, Paddington, London, W2.

POSTDOOTORAL RESEARCH SCIENTIST to Join a team engaged in applying biophysical techniques to problems of developmental biology; the research will involve studies of interaction phenomena between macromolecules and tissues, and of factors concerned in the control of macromolecular synthesis—The Director, Strangeways Research Laboratory, Cambridge.

RESEARCH ASSISTANT (graduate biochemist, preferably with experience in hormonal control of mineral metabolism) at the Nuffield Institute of Comparative Medicine, to undertake metabolic studies in relation to bone diseases in primates—The Establishments Officer, Zoological Society of London, Regent's Park, London, NW1.

RESEARCH ASSISTANT (with a degree in biochemistry or physiology) for work in zonal centrifugation of kidney cell fractions—Dr D. Robinson, Queen Elizabeth College (University of London), Campden Hill Road, London, W8.

HOW TO BUY NATURE

Volumes start in January, April, July and October, but subscriptions may begin with any issue.

The direct postal price per subscription for one or two copies of NATURE each week is:

*12 MONTHS (52 issues and 4 indexes)

Great Britain and Eire£14.0.0 ea	
United States of America(by air freight)\$48 ea	ach
Canada (by air freight) \$52 ea	ach
Elsewhere overseas by surface mail£14.0.0 e.	ach
Zioonia, a zina zina zina zina zina zina zina zi	

(Charge for delivery by air mail on application)
*Shorter periods pro rata. (Minimum three months.)

MULTIPLE SUBSCRIPTIONS

For subscribers who take more than two copies of NATURE each week these reduced annual rates are offered:

12 MONTHS (52 issues and 4 indexes)

Number of Copies	G.B. &	U.S.A. Canada		Elsewhere	
	Eire	(by air freight)		(surface mail)	
3–5 6–11 12 or more	Each £13.10.0 £12.15.0 £12.0.0	Each \$46.50 \$44.50 \$42.50	Each \$50.50 \$48.30 \$46.00	Each £13.10.0 £12.15.0 £12.0.0	

Multiple subscriptions must run concurrently. Every copy will be posted separately, and for speed of delivery each subscription can be addressed to a different individual, or department at the same address. (ZIP essential for U.S.A.)

Another Record

You can now have a Unicam Recorder to match the high performance of your Unicam Spectrophotometer. Fully transistorised, with fast pen-response and negligible dead-band, Unicam potentiometric recorders are designed for precise spectroscopic applications. They will also perform many general functions

in your laboratory.
You have the choice of two versions—SP20 with conventional strip-chart recording—SP21

with both strip-chart and flat-bed recording. Each version has six chart speeds, full span zero control, alarm contacts and provision for remote control. Additional motors to increase the range of chart speeds can be provided. An event-marke pen can operate in all recording modes. A Unicam Recorder will be a valuable addition to your infrared, ultraviolet or atomic absorption analytical system. Send for details today.

Put out no Flags

GREAT aircraft have something in common with great ships, and some of this was clearly apparent last week on the occasion when the first prototype of the Concorde aircraft emerged for the first time from its hangar at There were flags, military bands and speeches, some pompous and some silly. For a time, at least, even those who are accustomed to ask whether aircraft like the Concorde can ever be commercially successful may have found themselves catching their breath with the majesty of everything. Will that aircraft really be the first commercial supersonic transport? Will it earn valuable foreign exchange in huge amounts for two European countries much in need of that commodity? Or, even if it turns out to be a commercial flop, will it somehow earn reputation instead? A tear-jerking roll-out, the anti-climactic aeronautical equivalent of the launching of a ship, is hardly the time to be asking questions like these in anything but a respectful tone of voice. But that brave day is now well past, and it also happens that there are now urgent reasons why the British Government for one should make a careful appraisal of what the Concorde project is likely to achieve. Not even the most devout aircraft modeller should be surprised if there has recently been another flood of rumours that the British Government may now, at last, withdraw from a project which it has regarded with distaste ever since 1964. As it happens, however, the set of questions which the first appearance of the Concorde has provoked are a small part of the general problem of how intermediate nations such as Britain should somehow seek to manage their technology.

For intermediate nations, the case of the Concorde is an object lesson in the difficulty of knowing just what an intermediate nation should do with its technical resources. For one thing, the project is a great technical adventure which has done much to stimulate industry in Britain and France and which may yet win modest profits as well. But the project is also a great gamble. Anything may go wrong between now and 1971, when the first aircraft are due to enter service with the airlines. The steady erosion of performance which has marked the past year's experience may, for example, continue and even accelerate. Already the fully laden weight has increased from 250,000 pounds to 376,000 pounds, while the number

of passengers and the cruising speed have been marginally reduced. Given that the aircraft will not leave the runway at Toulouse for another six months, is it any wonder that people are asking what kind of a performance will be left by 1971? The fact that the Boeing Company seems also to be having difficulties in the design in the United States of the supersonic transport due to enter service in 1975 may be a comfort to those directly engaged in the Concorde project, but it serves only to emphasize to other people the hazards of this novel technological field. On technical grounds, the Concorde must be something of a gamble.

Even if the Concorde is an outstanding success as a flying machine, however, there can be no assurance that it will prove to be commercially successful. Indeed, it seems to be quite openly acknowledged that the cost of research and development will not be recovered by the sales of completed aircraft. So far, the British share of the development programme has worked out at less than 40 per cent of the £250 million contracted for under the agreement with the French Government. But the number of aircraft on order is still less than eighty, while even the most optimistic of the Concorde salesmen are not at this stage allowing themselves to dream of selling more than 200 aircraft. Evidently there is not much scope for recovering initial costs of between £4 million and £8 million an aircraft without pricing the Concorde right out of the market in which it makes most sense—the busy long haul routes such as those across the Atlantic. This is why a good deal of argument in favour of the Concorde, in Britain at least, now centres on the view that even if the financing of Concorde is enough to make accountants' hair stand on end, the aircraft (if successful) would bring in lots of foreign exchange. Specifically, and from the point of view of Britain alone, the expenditure of £250 million on research and development may—with luck enable the aircraft industry to earn up to £800 million or so in foreign exchange spread over the decade of the seventies. To begin with, it is only proper to acknowledge that this is tantamount to a form of devaluation—goods are being sold abroad at less than their true cost. More important, the potential benefits seem hardly worth the expenditure. Where else could governments afford to pay export subsidies of 30 per cent or so to particular industries? And are there any circumstances in which such a course would be considered when the chances of winning a reasonable return on the funds laid out are as hard to calculate as

The article on SI units advertised last week will now appear on Dec. 30.

with Concorde? In reality, of course, there are many safer and more profitable ways in which public expenditure could bring in foreign currency in large amounts.

In these circumstances, it is not surprising that the British Government is continually looking quizzically at the Concorde project. And it is natural that these inclinations should be particularly noticeable at times of economic stringency, when the hunt is on for almost any way of reducing the scale of public expenditure. In the present climate, it is extremely hard to see how the Concorde can survive for long. There is no need to say hard things about the aircraft, or about the difficulties of knowing how it could be made to fly over populated territories without causing an intolerable nuisance, to know that the game is hardly likely to be worth the candle. No doubt it will be sensible to wait a few months, until there is some experience of how the aircraft behaves in flight but before the heavy costs of an extensive testing programme have begun to mount up. By the summer of 1968, however, it would be entirely sensible if the British Government had found some graceful way out of what it has considered for three years to be an uncovenanted albatross around its neck. By that time, no doubt, there will be so many cancelled projects of one kind or another that the mere cancellation of Concorde may be a comparatively unspectacular affair.

But if, in the months ahead, it comes to seem comparatively easy for the British Government to withdraw from the building of the Concorde, there will remain the long-standing problem of how to avoid similar entanglements in the future. The international character of the venture is not by itself discouraging, for it has yet to be demonstrated that the costs of Anglo-French collaboration have been greater than would have been the costs of strictly national programmes for the development of supersonic aircraft. The real trouble is that projects like Concorde are at once too speculative and too inflexible for nations such as Britain prudently to undertake. So much is clear from the way in which the Anglo-French consortium has had to put all its efforts into a Mach 2 aircraft, and in the process deny itself the chance of rewards if the American choice of Mach 3 or thereabouts turns out to be more fortunate. In other words, the collaboration on Concorde is a gamble in which the participants are denied an opportunity to hedge their bets. But the gamble also has too much the sense of being an all-or-nothing choice. There is very little profit in stopping half-way.

These awkward circumstances should be a clear indication of the directions in which intermediate nations should seek to edge their policies on technology. Quite apart from calculations of the profitability or otherwise of particular ventures, there are also important strategic advantages to be had from development projects which are flexible in scale and which are also so well within the compass of the nation concerned that it can reasonably hope to spread some of the risks which inevitably attend advanced development of any kind. By this test, there is clearly much that is dubious about the British Government's hope to see the emergence of a British computer industry able to service the whole of Europe in competition with companies from the United States and from France. That, too, is a gamble, though by now so much money and prestige has been committed to it that it would be a pity to see it fail. The development of hovercraft is similarly a case in which too many eggs may rest in the same basket. This is the kind of project in which it would have been more sensible to develop some other form of fast sea propulsion in parallel with hovercraft. All these, however, are projects in which everything hangs on the problematical outcome of a long programme of research and development. cleverly arrangements may be made to see that all likely successes are well supported, rewards do not come until a long programme of work has been completed. It would be much safer, and in the long run more profitable, if more could be done to support ventures in which even small expenditures could bring rewards. This is why there is a case for asking that governments in intermediate nations should be more assiduous in the encouragement of comparatively humdrum activities such as the improvement of electrical generating machinery, and less anxious to keep up with more powerful competitors in the development of the most radical innovations. It is true that there is always a chance that these projects may become enormously rewarding, but this is always something of a gamble.

More Ructions about the Library

THE members of the House of Lords are fond of saying that, even if they have long since lost most of their pretence to be political powers in the land, they are at least the best debating club in Britain. Unfortunately, the debate on December 13 about the issue of the library at the British Museum was almost by itself a proof that even this conceit is unjustified. The debate was sadly one-sided and unconstructive. It provided an opportunity for several of the trustees of the British Museum to let off the head of steam which has been building up in the weeks since the Secretary of State for Education and Science, Mr Patrick Gordon Walker, casually put an end to the plans which the trustees

have been nourishing all these years, but that is not the kind of debating society which the House of Lords would like to be. To be sure, it is asking almost too much of flesh and blood to hope that Lord Radcliffe, the chairman of the trustees, would fail to take this opportunity to give the Government a verbal trouncing, but was it really sensible of the other trustees to spend so much time on expressions of defiance and, comparatively, so little on asking what should happen now? It may even have been a mistake to let it be so widely known that the trustees as a whole will probably resign if the British Government seeks to separate the library from the British Museum and then to use it as

the nucleus for a national library away from Bloomsbury. Certainly it was a mistake for Lord Eccles, once a Minister of Education, to make the absurd declaration that "Under the existing British Museum Act, no minister has any power to move a single volume from Bloomsbury to Bayswater, or from either place to some other place". New legislation is easier to come by than are good ideas.

In the event, of course, everything will depend on what the committee under Dr F. S. Dainton recommends, and one of the useful products of the debate in the House of Lords was the announcement by the Government of the four members of the committee who will share the unenviable task of deciding what should happen now. They are all distinguished men, although none of them is a librarian. Their biggest difficulty in the six months or so ahead will be somehow to pick out solid ground among the mass of contradictory opinions which must surely assail them. The trustees of the museum would be well advised if they could somehow bury their chagrin at how the Government has dealt with them, for, if they fail to present a rational case for the preservation of their own version of the status quo, the chances are that the decision will go in favour of a separation between the museum and the library. Indeed, whatever strength there may be in the case the trustees have hiding up their sleeves, the advantages of a properly unified library will outweigh the advantages of a combined museum and library. In other words, there is a danger that the trustees' bluster at the way in which the Government has behaved itself will very soon seem to be bluster at the awkward implications of logic.

Small Cheer for Non-proliferators

It is something of a puzzle to know whether to be cheerful or otherwise about the results of the long session of the United Nations Committee on Disarmament which adjourned its meetings in Geneva last week for the Christmas holidays. For the past few weeks the chief participants at Geneva—the United States and the Soviet Union—have been suggesting that agreement on a non-proliferation treaty might have been close at hand. But it seemed to have become plain, by the end of the session, that the more cheerful predictions were based on the assumption, or perhaps the hope, that serious problems would somehow vanish. Yet there seems no real prospect of a rapid solution to the problem which dominated the last few meetings of the committee—the issue of whether the Euratom countries should be allowed to substitute to some degree inspection of nuclear installations by Euratom itself for the inspection by the International Atomic Energy Agency that will apply to everybody else. France is not, of course, represented on the committee, but it seems that the Federal Republic of Germany has not been the only sponsor of the view that Euratom inspection should be allowable. The Italian delegation at Geneva seems also to have been working for this -objective.

Perhaps the most alarming feature of this development is that the European advocacy of Euratom

inspection has come as such a surprise to the nuclear powers. It is now roughly a year since the argument was first raised outside the meetings of the committee on disarmament. The fact that Euratom itself seems to be in a sickly condition as a means of prosecuting research and development in nuclear energy is neither here nor there—the Euratom safeguards system is still a going concern. But the Soviet Union is unlikely to be able to agree to much less than full-blooded inspection by the International Atomic Energy Agency in Vienna. Evidently the British and American governments were hoping to take some of the edge off these proposals by announcing that civil nuclear plants in Britain and the United States would be subjected to inspection by the international agency even though nuclear powers would not formally be subjected to inspection of any kind under the terms of the treaty which have so far been negotiated. The trouble, of course, is that even such a gesture of voluntary submission may cut both ways. Although nations in Europe concerned about the supposed potential loss of commercial secrets might benefit from knowing that the United States and Britain would run similar risks, the Soviet Union is likely only to be embarrassed by this precedent, and there is no suggestion that France would be prepared to follow suit. In all these circumstances, it would not be entirely surprising if the next meeting of the disarmament subcommittee, provisionally set for January 19, 1968, is eventually postponed.

Less for United States Science

THE war in Vietnam and the need for economic restraint at home have combined to squeeze United States spending on research and development quite drastically. Although spending in other directions has also been cut, research and development seem to have been hardest hit. In spite of a request for \$5,100 million for NASA, for example, Congress approved only \$4,588 million, the deepest cut it has ever made in the United States space effort. And the Department of Defense, although it emerges with a total budget at about the same level as last year, has been told to cut its support for basic research from \$399 million to \$361 million, more than 10 per cent. This was part of a much more drastic cut demanded for the whole Defense Department—it was asked to cut some \$2,000 million from its total budget, but only in activities unconnected with Vietnam.

Other agencies were treated more gently. Atomic Energy Commission got an allocation of \$2,509 million, a 14 per cent increase over last year, although less than the original budget request. High energy physics research showed a \$10 million increase, and support for controlled thermonuclear fusion research went up from \$22.6 to \$26.2 million. Reactor development was increased by about 10 per cent, to \$507 million, and the Plowshare programme, which seeks to devise peaceful uses for nuclear weapons, went up from \$13.3 million to \$20.7 million. In other departments, the rule of thumb seems to have been to cut down programmes to a size midway between the actual figures for last year and the Administration's suggestions for this. Exceptions were the individual institutes within the National Institutes of Health, which each got exactly what had been requested. The

National Bureau of Standards, with \$32.5 million, is marginally worse off than last year. The National Science Foundation, on the other hand, has done rather better this year than last. Its budget will be \$495 million, an increase of \$15 million over last year. Elementary and secondary education shows an increase of over \$200 million, to \$1,667 million, but higher education has been cut by \$20 million, to \$1,158 million.

In many cases, further cuts are threatened by a plan recently announced by the Administration. intended to force agencies to cut their expenditure below the levels proposed to Congress by the President. Under the formula, some programmes are to be cut by 10 per cent of programme costs and 2 per cent of payroll costs. The idea behind the reductions was to try to persuade the House Ways and Means Committee to look more kindly at the Administration proposal for a 10 per cent tax increase. The committee has so far remained unconvinced, preferring to cut public expenditure rather than raise taxes. Much will depend on whether the projected budget deficit for this year is greater than that for last year or not. In some cases the cuts imposed by the Administration will be less severe because of the reductions imposed by Congress, but the AEC, for one, seems likely to be a sufferer if the plan goes ahead.

The effects of these cuts will not be fully appreciated in the universities until the spring, when arrangements for the academic year beginning in September 1968 will have to be made. Administrators seem to be most uncomfortable about the possibility that smaller research budgets will make it much more difficult to retain new graduates as assistants, who shoulder collectively a good deal of the teaching burden at a great many universities. But there is also talk of how laboratories dependent on the mission-oriented agencies for finance may have drastically to alter plans for the years ahead. In the circumstances, it will not be much of a surprise if many organizations find themselves running for cover at the National Science Foundation.

British Computers

For some months, the leading British computer companies, International Computers and Tabulators and English Electric/Elliott Automation, have been coyly denying rumours of a liaison. But now the secret is out—at the annual general meeting of ICT on December 13, the company chairman, Colonel A. T. Maxwell, admitted that discussions were in progress. The matchmaker has been the Ministry of Technology, which has never hidden the fact that it is interested in a rationalization of the British computer industry. So far, the Ministry says, only ICT, English Electric and itself are talking, but it is probable that other British companies are taking more than a passing interest. The talks, which have been in progress for a few months, are likely to be concluded within "months, rather than weeks".

The argument used in favour of the merger, if it comes about, will be that the UK market is too small to support two companies competing across the board. Too much duplication of research and production, it is said, is more than Britain can afford in a market still dominated by United States companies. As well as the production of central processors, both firms make a wide range of peripheral devices. Although ICT estim-

ates that the British market is going to show a growth rate of around 15 per cent for the next few years, American competition, chiefly in the form of IBM, is likely to swallow up about half of that. ICT says that it has one-third of the British market, the same proportion as that taken by IBM. If this sounds like drastic American penetration of the British market, it is worth remembering that IBM has something between 70 and 80 per cent of the world market; judged on this scale, the performance of the British companies in recent years has been quite respectable.

English Electric, although it is still making a few Leo and KD machines, is concentrating now on its System 4 range. There are several models in this ambitious range, the first to use wholly integrated circuitry, and they range from the 430, which costs about £100,000, up to the 475, a multi-access computer costing around the £1 million mark. English Electric says that it has had orders for the range worth £25 million. The plans for a big computer, originally proposed by Elliott Automation before it was taken over by English Electric, now seem to be in the melting pot, and a joint planning group has been set up to The integration of decide what should be done. English Electric and Elliott Automation is now going ahead quite quickly, but there is still work to be done, including most probably the unravelling of an arrangement negotiated by Elliott's with National Cash Register.

ICT also makes a full range of computers, less ambitious technically than the System 4, but successful commercially. At the annual general meeting last week, Colonel Maxwell was able to announce cheerful increases in profits, up from £2.22 to £2.87 million.

ICT, then, is in better shape than before, while English Electric is still struggling. No amount of confident talk can conceal the fact that substantial production difficulties have arisen with System 4. În the circumstances, ICT sometimes looks as if it is waiting for English Electric's position to get weaker still before it steps in with a firm merger offer. This may be the reason why Colonel Maxwell assured his shareholders that ICT would be the largest single component in a combined company. Quite clearly neither company is as keen on merger as the Government, and it is probable that some "lubrication", in the form of cash from the Industrial Reorganization Corporation, will be needed before terms are finally agreed. But the fact that the two companies market directly competitive ranges means that no easy merger is likely—in this case there can be no talk of the two ranges being complementary. The chances are that one would have to go.

Proton Accelerator Delayed

The meeting of the council of Cern held at Geneva a week ago served principally to confirm what has been clear for some weeks now—that the 13 members of Cern are not yet able to commit themselves to the project for building a 300 GeV proton accelerator. That said, it does appear that the tone of the meeting was cheerful and even constructive, so that even though the deadline originally set for a decision about the machine has now been passed, the hiatus in the planning is more accurately described as a postponement than an abandonment.

Several developments have helped to interrupt the smooth attainment of the timetable spelled out a year ago by the council of Cern. For one thing, there has been the devaluation of sterling, which explains why the United Kingdom and Spain were not able, at the council meeting last week, even to approve the budgets for 1968—197.5 million Swiss francs for the basic costs of the Meyrin laboratory and 28.43 million Swiss francs for the programme connected with the Intersecting Storage Rings. The British Government is particularly concerned with the international consequences of devaluation, for something like £5 million a year out of the annual budget of £33 million of the Science Research Council is at present allocated to overseas expenditure. The question which has to be settled before it is possible for the Science Research Council to participate even in the ordinary activities of Cern is whether such a large and uncovenanted increase of real expenditure is possible without harming the rest of the council's work.

The 300 GeV project seems also to have been held up by doubts in West Germany about the desirability of the particular design worked out by the European Committee for Future Accelerators and published in Especially since details of the design of the United States 200 GeV accelerator at Weston, Illinois, have been made known in the past few months, there have been some suggestions that Europe might hope to obtain better value for money by building a somewhat simpler machine. The meeting of the Cern council last week seems to have reaffirmed the earlier view that a European machine should be generously provided with experimental facilities of all kinds, but at the same time it seems to have been acknowledged that the studies of the 300 GeV problem will be continued at Cern, so that the design already published must be regarded more as a feasibility study than as the detailed prospectus which it seemed to be a few months ago. To this end, the council last week did approve an allocation of \$4 million for the continuing programme of planning and design. Although it is theoretically possible that a final decision on the accelerator could be taken at any one of the four council meetings due to be held in the year ahead, the optimists who hope that everything will be settled by June are likely to be disappointed.

More about Stansted

London's third airport was discussed at Westminster again last week, this time in the Lords. Lord Macpherson of Drumochter initiated the debate, the first in the House of Lords on the subject since the White Paper was published in May with the decision to build at Stansted. In the eight hour debate only five of the thirty-one speakers supported the government's decision. The feeling among the rest was not that Stansted was necessarily the wrong site for the airport, but that public opinion had not been satisfied that the choice was the best. The facts behind the present situation were put forward—the Interdepartmental Committee report of 1963, calling for an inquiry; the inquiry inspector calling for a further review of the problem; the government review held in private coming out in favour of Stansted. Doubt about the decision to build arose because the final review was held in private, particularly as the reasons for this privacy were inconsistent. The White Paper stated

that the urgency of the problem precluded a public inquiry, which anyway would produce no additional facts. In the debate, however, Lord Kennet said, for the government, that the proper discussion of defence issues could not be carried out in public. Viscount Dilhorne submitted that because a considerable number of new facts had come to light since the original inquiry, it should be re-opened in public, in the manner recommended by the Franks Committee. Only in this way would "broad justice to those affected" be done and be seen to be done.

The White Paper suggested that a second pair of runways would be added to the two originally planned for Stansted. This proposal was not considered at the original inquiry, and would significantly alter effects on the area. Silverstone received a passing mention as an alternative, but most attention was focused on Foulness. Included in the cost of an airport at Foulness was £25 million (a much questioned figure) for moving the Shoeburyness firing range. Beswick, putting the government's case, admitted he had "never treated this one very seriously". His main objection to the building of an airport on land reclaimed from the sea was based on the length of time it would take, quite apart from the time involved in holding a public inquiry. Lord Beswick believed the loss of food production from building an airport on good Stansted land, estimated at £1 million a year by Lord Butler, would be far outweighed by the foreign currency gained from a third airport built in the early seventies. If there was no such airport by 1977, on British Airports Authority estimates, nearly 3 million overseas visitors would have to be turned away, losing Britain an estimated £36 million in foreign currency from landing fees, spending money and airline earnings.

Lord Plowden described the White Paper as "full of statements presented as facts which the public are expected to accept". He remarked on the paucity of information on cost-benefit analysis. The social costs involved might be so heavy that the country could well afford the time to investigate the situation again. The theory that Whitehall is always right was questioned by Lord Balfour, who quoted as an example the speech he himself made as Minister of Aviation in 1939, which was full of miscalculation about airports.

The belief of the Lords was that there is still time to reconsider the Stansted decision. The most important product of the whole debate was the announcement by Lord Kennet that the government is intending to improve the planning laws for projects on the scale of airports. Under the present system planning permission is sought for one specific site only, but the proposed Town and Country Planning Bill would allow alternative sites to be listed in the request for planning permission. An inquiry would then determine which of the alternatives was most suitable before the present procedure is gone through.

Changing Units

A COMMITTEE appointed by the Ministry of Technology to investigate the adoption of metric units has reported that, unless steps are taken now, an important sector of the economy may be slow to accept the new units. The committee, formed by the CBI at the request of the Standing Joint Committee on Metrication, a

Ministry of Technology body, has investigated preparations being made in the non-industrial sector of the economy, which includes bottling and packaging, the retail trade and transport. Because this sector is not the direct responsibility of any government department, the CBI has concluded that the change to SI units is not being properly organized. The CBI is alarmed that the advantages to industry of the change to the new units will be wasted because the packaging industry, and the retail outlets, will still be using Imperial units.

In fact the change to SI units is happening more rapidly than most people suspect. As well as the encouragement given to the scientific journals by the Royal Society (Nature, last week), the Department of Education and Science and the Confederation of British Industry are well aware of the implications of the change. Abroad, the change is going even faster—by 1975, SI enthusiasts say, only the United States and Canada will be using Imperial units, and they can be expected to change rapidly as soon as they begin to feel isolated. In Britain, the timetable for the change was set out in a parliamentary answer by Mr Douglas Jay when he was President of the Board of Trade. He said that by 1975 the majority of British industry should have moved over to SI units. Unfortunately, he said nothing about the non-industrial sector of the economy, and no government department has taken it under its wing. For this reason, the CBI has been driven to suggest the establishment of a Metrication Board, rather similar in structure to the Decimal Currency Board. The board would have as its responsibility the co-ordination of metrication in the various parts of the economy which have so far been lagging. For one thing, the SI system proposes a standardized set of package sizes, but the packaging industry is not yet planning effectively for the change. another, all the road signs in the British Isles will need to be changed from miles per hour into kilometres per hour. Some observers, alarmed at the slow progress, are inclined to point out that when Sweden changed from the left to the right side of the road it was after four years of the most intensive planning. Similar planning, they suggest, will be needed for the successful adoption of the metric system.

The proposed Metrication Board, the CBI says, should not be a part-time body. What is needed is a body representing both government departments and the interests concerned, with a full-time chairman and secretariat. And, if the progress towards metrication is not to be slowed down, the board should be set up as a matter of urgency.

Instruments for Technology

THE Scientific Instrument Research Association (SIRA) spends the £0.5 million it receives each year from its members and from the Ministry of Technology on trying to promote measurement and control technology in science and industry. But the association suffers because most of the industrial companies working with anything like advanced technology are able to look after their own measurement and control systems. The SIRA laboratories are on the whole left with the small fry—the craft industries. For them SIRA does a good job. It has, for example, taught British biscuit manufacturers how to measure the water content of

biscuits by measuring colour. It has also devised ways of testing coin blanks before minting and has used a laser for micro-machining.

Given the dominance of the German and Japanese optical industries, it is perhaps surprising that one of the outstanding achievements of SIRA has been the development of two very sophisticated machines for testing lens performance. This work began 9 years ago with a contract from the then Ministry of Aviation, but now receives international sponsorship. One of the machines, now commercially available and slowly finding a world market, measures the optical transform function of a lens so that the quality of the image can be specified objectively. The other, a pupil scanning lens tester, measures the extent to which the wave front emerging from a lens deviates from being spherical. A computer attachment can then calculate the various aberrations present in the lens.

SIRA hopes that this work will eventually lead to a much needed international agreement to specify lens performance objectively, in terms of optical transform functions.

No Buns for the Elephants

THE decision of the council of the Zoological Society to ban all feeding by visitors at London Zoo and Whipsnade Park from the beginning of 1968 is the final stage of the policy adopted in 1965 in the interests of the health and general welfare of the animals. The policy of no feeding has been introduced gradually as new animal houses have been opened, and now the ban is to apply to the remaining animals, the most important of which are the monkeys and apes, some of the bears, the elephants at London and the herd animals at Whipsnade.

Visitors to the zoos will find with their guide books and pamphlets a leaflet telling them not to feed the animals and explaining why the ban is considered necessary. The two zoos have veterinary and supplies officers who know the nutritive requirements of the animals and who try to provide them with a balanced diet. When the visitors feed the animals, unbalanced diets are unavoidable, and these are not good for the animals, who may do themselves harm, sometimes serious, by over-eating or eating proffered food which is quite unsuitable for them. There may also be accidents, not always as serious as the death of Dicksie the elephant this year, when she fell into the ditch around the enclosure while stretching out for food.

The visitors too will be safer when the ban is enforced; during one year at London 180 people have been bitten by monkeys, parrots, cockatoos, ponies and other animals. During the same year elephants at London seized fourteen coats, twelve handbags, ten cameras, eight gloves and six return tickets to Leicester, damaging them all beyond repair.

The council of the Zoological Society also says that the control of feeding in zoos is necessary to create conditions in which the animals may breed and rare species may be conserved. Some animals are now so rare that they are only available from surpluses bred in other zoos. These include the orang-utan, the European bison and Père David's deer. The last two are now extinct in the wild, and the Zoo is determined that unbalanced feeding should not be allowed to make them extinct in zoos as well.

This policy brings London and Whipsnade into line with almost all continental zoos, which have already banned feeding by visitors. Chester and Edinburgh also enforce the ban, and Bristol will be doing so at the beginning of next year. Zoos which have already adopted the policy have found that animals are much fitter and that the volume of deposited litter has decreased considerably. The problem of educating the public to resist throwing buns, nuts and other food to the animals is considerable. As well as the leaflets there will be more "no feeding" notices, and, although nobody will be turned out of the zoo for feeding the animals, offenders will be asked to stop by watchful keepers. Nevertheless, London Zoo expects it to be three years before its annual total of two million visitors are all persuaded to observe the ban.

Inexpensive Technology

A British group set up to promote technological development in backward parts of the world has just published an unusual report. Instead of familiar and extravagant declarations of what could be done by setting up large nuclear power stations linked to desalination plants, or by harvesting the sea, the report concentrates on much more mundane pieces of equip-The group is the Intermediate Technology Development Group Ltd, and the report—Tools for Progress—lists agricultural and industrial equipment which can be bought for modest amounts, within the budgets of developing countries. The director of the group, Dr E. F. Schumacher, says in the introduction to the report that "It is easy to think of the progress that would be possible if the majority of the world's peasants had the means of making full use of modern science, and the necessary knowledge and method to boot. But this means solving the problem by assuming it away. The crucial question is rather how to help the majority to help themselves.'

The group has set out to do this by making people aware that cheap methods, tools and equipment do exist, and that these can be made available where they are needed. Tools for Progress is the result of a survey made of British manufacturers, and includes short descriptions and pictures of most of the tools which fall into the low cost category. The guide also lists the manufacturing agents in developing countries, and British organizations concerned with development problems. Three thousand copies of the booklet are to be distributed to banks, co-operatives, government officials and the like in developing countries, and further copies can be had for 15s. each.

The guide is a cheerful mixture of products, some of them looking rather old-fashioned. But all look purposeful and sturdy, and where prices are quoted (it is a pity they are not given throughout) they seem reasonable. It is possible, for example, to buy a windmill pump capable of pumping 1,130 gallons per hour for £120, from H. J. Godwin Ltd. A Kentish foot loom can be bought from Douglas Andrew Ltd for £80. The group plans to produce revised editions of the guide periodically, and would welcome helpful suggestions.

Investigating the Earth

THE International Upper Mantle Project, begun in 1963 to co-ordinate international research into the

geophysics of the region just below the Earth's crust, is now well under way. Among the techniques used have been the measurement of heat in deep bore holes, aeromagnetics, and the measurement of gravity from orbiting satellites, the last of these particularly requiring the co-operation of many countries. Large numbers of research workers have converged, naturally enough, on the East African rift system and the Mid-Atlantic Ridge, but geophysical understanding of great areas of the world has already been increased. The interim report on the Canadian effort, for example, is able to announce that: "Canadian scientists can begin to talk knowledgeably of the geological and geophysical properties of the entire Canadian crust".

It would, perhaps, be invidious to mention any individual piece of research completed so far, but as far as Britain is concerned, there are a number of projects, either approved or under consideration, which promise to be of great interest. One of these is the planned aeromagnetic survey of the rift valley in the Red Sea and Ethiopia. This is a region peculiarly unsuited to ground observation but in which there may well be magnetic anomalies similar to those discovered in the Mid-Atlantic Ridge, where it was found that the magnetic irregularities were mirror-images of each other on either side of the ridge. The Natural Environment Research Council has given a grant to support this work. There is also a plan, not yet approved by NERC, to take measurements across the rift valley further south over a period of years, and so detect earth movements, a technique which has provided encouraging results in Iceland. experiment on the rift would be carried out by associate teams from some British universities, including Birmingham and Durham. This plan is to investigate the geology of Lake Victoria by analysing the seismic effects of explosives dropped into the lake.

National Parks

THE National Parks Commission has in the past few months produced reports on the Brecon Beacons and the coasts of Hampshire and the Isle of Wight. Both documents are concerned with conservation and each is one of a series on similar subjects. The detailed guide to the Brecon Beacons is the fifth in a series of ten on the National Parks, while the report of the Regional Coastal Conference on Hampshire and Isle of Wight Coasts is the second of a series on coastal preservation and development. National Park guides are designed for the visitor, to enable him to understand and appreciate the countryside better. Coastal conferences, on the other hand, are designed to produce a comprehensive survey of the whole coastline so that a co-ordinated policy can be developed.

The National Park in the Brecon Beacons, with more sheep than people in the upland regions, is unindustrialized and largely unspoilt. The authors of the guide hope that the visitors who come will keep it that way, but endeavour to increase appreciation of the area with this detailed description of things to see, whether living or historical, and things to do, in the way of pony trekking or caving. The Palaeozoic rocks of the area are described; many of the 200 kinds of birds and their localities are listed, as are animals, insects and flora. Scheduled ancient monuments, places of interest and Welsh names in the park are

also given. The guide is an interesting and comprehensive account of the area.

The coastal conferences were designed with a more definite aim in view. Studies of coastal areas by the local planning authorities were first called for in 1963 by the Ministry of Housing and Local Government. Development plans were to be considered in relation to conservation of natural attractions, places and nature of amenities for holidaymakers and areas of special scientific interest. The ministry asked the National Parks Commission to arrange conferences to coordinate the plans of the various local authorities. In the meantime, additional studies are in motion, investigating aspects of the problem of coastal development in terms of social, economic and recreational factors. Places of scientific interest are being identified and classified by the Nature Conservancy. The conference on Hampshire and the Isle of Wight, which was held in Southampton in June 1966, began with a reminder that industrial requirements must be considered alongside any developments for holidaymakers. The conference proceedings form the first part of the report, the rest being given to written reports from planning officers in the area, statistics of land use of the 133 miles of coastline, and the movement of retired people to the area, with accompanying social problems. A map summarizes the development and protected areas along this section of the coast, with figures for visitors in main resorts. Coastal eyesores such as wartime remains, rubbish tips and abandoned vessels have also been listed. These are encouraging steps in coastal planning and improvement. While waiting for the results of all the conferences, the ministry has called for a "holding operation" so that the coasts are protected until a definite policy has been worked out.

Research in Education

THE twenty-first annual report of the National Foundation for Educational Research in England and Wales has recently been published. During the year the foundation transformed itself into an incorporated organization (a company limited by guarantee). The purpose of this change was to give the foundation a separate legal existence. Sir Francis Hill, chairman of the Executive Committee, retired and was replaced by Sir Alan Lubbock.

According to the report, these changes in the foundation's financial and administrative structures have been matched by a continuing process of change in the whole field of research in education. Between 1966 and 1967, two bodies—the National Advisory Council for Educational Technology and the Committee on Research and Development in Modern Languageswere set up in addition to the Schools Council. Each of these has considerable government finance behind it and is likely to undertake or commission research work which will involve the schools. It has also been suggested that something similar should be set up for teacher education and training. Another new development is the setting up of a Planning Branch by the Department of Education and Science to undertake research in education through its own staff and through staff specifically employed for particular pro-This new department, it is stated, will concentrate on relatively short-term studies mainly in the field of economic research.

Three new developments which reached an advanced stage during the year were: the first issue of the foundation's newsletter, *Educational Research News*; the development of research paperbacks which are now in the press; and the production of pamphlets, setting out the practical applications in schools of the foundation's recent researches, which will be ready in the new year.

The foundation has supported mathematics research, reading research and research on the teacher's work and training. In addition, research projects in technical and further education have been continued. A Constructive Education Project, sponsored by the Home Office and the Department of Education and Science, is investigating the influence of schools on children with particular reference to their achievements, attitudes and behaviour. The project, which was started in 1964, will continue for eight years.

Over the two years from 1965 to 1967, sponsors have increased finance for projects by 125 per cent and this now accounts for a considerable portion of the foundation's finances. Generally, finances for the work of the foundation are drawn from two main sources, subscription income and contract finance, both of which are controlled by the board.

During the year the basic subscription income increased slightly to £64,133 and income from publications rose significantly to £8,600. Work on sponsored projects increased by approximately 23 per cent over the previous year while grant-in-aid from the Department of Education and Science remained at £20,000.

Currents in the Atlantic

THE research vessel Discovery was brought back to her home port, Plymouth, on Monday this week after a two month cruise in the east Atlantic under the leadership of Dr J. C. Swallow of the National Institute of Oceanography. Most of this cruise was concerned with taking an initial look at deep current patterns over a reasonably extended period, now that the techniques for doing this are becoming available. The basic current meter used on this cruise is a device made in the United States, but the ancillary equipment which has enabled the maximum information to be derived from it has been specially developed at the National Institute of Oceanography. Anchored deep current buoys were put down on the flat "bottom plain" at the mouth of the Bay of Biscay. These were positioned about 30 miles from each other and made measurements at three levels—400 m, 1,200 m and at bottom water below 2,500 m. The deepest position was at 4,800 m where a buoy remained for 5 weeks. The others were in position for shorter periods but still of the order of weeks.

Because so little is known of the long term fluctuations of deep currents, three drifting floats given neutral buoyancy to remain at similar depths were used as a check for the buoy measurements. The floats contained an acoustic beacon with a range of 4–5 miles to show the way the instruments drifted in the current. Dr Swallow said he was surprised that there were not more fluctuations in the currents measured. Findings from the floats alone indicate that the deeper level currents tend to move faster, but from this cruise it was found that there was always a relationship of general direction between the three currents when

calculated over a period of several days. Current speeds were found to vary between 2 and 20 cm/sec. Subtler data from the continuous readings of the anchored buoys have yet to be analysed at Wormley. The hope is that from this initial experience a programme for immediately reducing data from the buoy recorders on board Discovery can be ready in time for the installation of a computer on board. This, it is hoped, will be working when the next deep current cruise takes place in about a year's time.

Launching a deep-sea buoy for current measurement from RRS Discovery (National Institute of Oceanography).

The ultimate object of this work is to investigate the relationship between atmospheric phenomena and deep water currents. It is expected that this interaction will be expressed as a time variation with a period of several weeks. Studies like these could eventually help with long-range weather forecasting.

High off the Ground

When Concorde made its first appearance at Toulouse on December 11, reporters and officials were dwarfed by the undercarriage, especially at the nose where the aircraft is 15.5 ft. off the tarmac. There are two reasons for this. Because of the delta design, the Concorde has a high landing angle, about 10° nose high. And because of this high nose angle, the nose has to droop 17.5° for the pilot to be able to see out properly when landing or taxi-ing. The design of this undercarriage, however, has not presented many problems to Messier and Hispano-Suiza, who were responsible for the nose landing gear and the main landing gear respectively, as the Concorde lands at 153 knots, not much faster than the normal landing speed of subsonic jet aircraft.

Concorde's drooping nose seems to be a common factor with all supersonic airliners. The winning US design, the Boeing 2707, has one, as did the Lockheed design. The Russian TU-144, another challenger to Concorde, also has the droop nose. The Concorde project is costing the French and British governments £250 million each. Each aircraft is expected to cost £7.5 million, including initial spares.

Report Justified

Nor many compilers of annual reports seriously consider whether their labour is worthwhile. Dr S. G. Burgess, scientific adviser to the Greater London Council's Scientific Branch, has at least tried to justify his annual report for 1966. He says it is only by collecting results of scientific studies and presenting a summary that it can be assessed whether the scientific branch is worth its keep. The report is published by the Greater London Council,

price 5s.

According to the report, some 124,672 samples were examined during 1966 by the scientific branch. These included asphalts, tarmacadams, plasters, plastics and putties; butter, blancmange powders and suet; insecticides, paints and rubber. Items which receive most attention in the report are: water pollution and sewage treatment, building materials for construction and maintenance, environmental studies, and general supplies and services. W. B. Chapman, the public analyst, has also included a report within the main one which refers to 3,727 samples received under the Food and Drugs Act. Dr Burgess has also indicated probable lines of progress for the following year.

Generating Neutrons

In an admirably clear-headed report, the Science Council of Canada has now recommended in principle the building of an intense neutron generator. A preliminary survey of the project, costing \$7.5 million, is to proceed forthwith. If this is favourable, present estimates call for a total of \$155 million to be spent

by 1973 in building the generator.

The intense neutron generator will be based on a 1 GeV proton linear accelerator. In 1952, W. B. Lewis of the Canadian Chalk River Nuclear Laboratories realized the significance of certain experiments carried out with high energy protons from the cyclotron at Berkeley. These experiments implied that, in a thick target of heavy elements such as bismuth, each proton would generate many neutrons. The neutrons could be used to generate fissionable material by neutron capture in elements such as thorium. The uranium-233 thus produced, when burned in a reactor, might lead to the production of more electrical energy than was used originally to accelerate the electrons.

Apart from its possible relevance to low cost power production, the generator will be a valuable research tool in its own right. As the source of intense fluxes of thermal neutrons, it is expected to have applications in solid state physics, nuclear physics and materials science. It will also provide intense beams of neutrons, muons and pions for use in nuclear probes and elementary particle studies. An important industrial application will be the production of high-grade radioactive materials of commercial value. A breakdown of the various uses and purposes of the ING attributes about 60 per cent of its probable value to basic research and 40 per cent to applied research.

In making its recommendation, the Science Council of Canada has also taken explicit account of the nonscientific benefits to be expected from the generator.

It points out that, for a country of Canada's size, a degree of specialization is essential if high standards are to be achieved. Standards of excellence in given areas will not only encourage scientists and engineers to stay in Canada but also constitute the only sure way of achieving results which are internationally significant and competitive. The ING project is related to an area in which Canada already has an important investment and an international stature. It will have an encouraging effect on those concerned with the basic research and engineering objectives of the project, and it is expected to have a substantial industrial fall-out. It does not duplicate research abroad, and should attract foreign scientists to Canada as well as placing Canada in a good position for exchanging research information with other countries.

Control of Malaria

THE World Health Organization has been so successful in eradicating malaria from certain parts of the world (particularly in Europe, where the number of malarial cases fell from more than four million to less than seven thousand in the first fifteen years of WHO's existence) that it can now turn its attention to the problem of keeping these areas free of the disease. Unfortunately, laboratory tests for detecting potential malarial carriers are not completely effective, and a person infected by a mosquito may remain a carrier for a very long period of time. Permanent immigrants are more likely to re-introduce the disease than tourists, and the WHO technical report devoted to the problem stresses the necessity of co-operation between government authorities concerned with health and immigration. But it is possible to contract malaria during a short stay in an infected region, and the report recommends that shipping companies be aware of the problem, and that passengers and crews should be instructed in the use of prophylactics. A new difficulty besetting health workers has been the increase in the number of Plasmodia resistant to 4-aminoquinolines. Fortunately, however, few resistant strains have reached malaria-free countries; WHO hopes shortly resume publication of its reports on the spread of the strains.

The measures Britain takes to keep out malaria are hardly exemplary. No checks for the disease are made on passengers coming from abroad—though the Board of Trade does issue advisory notices to shipping companies on the diagnosis and cure of the disease. Yet Britain has not been troubled by a malaria epidemic since 1921, and during the past ten years no cases have been reported. The reasons for this are partly fortuitous—Plasmodium falciparum does not usually survive in the mosquito long enough to be transferred to the next human host. This is not true of Plasmodium vivax, the malarial parasite endemic in Britain in the past but now imported by immigrants from India and Pakistan. Indian immigrants, however, tend to live in cities where the appropriate mosquito species are rare. In any case it appears that the mosquito population as a whole has been greatly diminished by farm insecticides—the use of which is not, of course, primarily directed against mosquitoes. Finally, as more and more people travel by air rather than by sea, the risk of passengers being infected with malaria en route and entering Britain as innocent carriers of the disease has

lessened. Not only do air passengers spend less time in infected areas, but aeroplanes and airports are rather easier to spray than ships and harbours.

Tissues in Store

THE problem of a Christmas present for the biologist who has everything might be solved by a glance at the catalogue of the Exotic Animal Tissue Bank. This is a collection of tissues which was established in September 1967 at the St. Louis Zoological Park, in St. Louis, Missouri, in co-operation with the Center for the Biology of Natural Systems at Washington University.

The tissues come from animals which have died in the zoo—the service operates as part of the zoo's research programme. There are now more than 1,000 specimens available to research workers, teachers and anyone else who would like them. Prices range from \$2.00 for 1–10 g to a minimum of \$25.00 for amounts greater than 1 g. Prices for whole organs weighing less than 10 g will be quoted on application. With each specimen comes a brief history, including the species, age, sex, treatment given and cause of death. Many specimens have already been distributed to workers in a wide range of disciplines.

Specimens are fixed in 10 per cent buffered formalin, or frozen or made into slides, and it is hoped to expand the service to include fixation for electron microscopy. Anyone wanting to look at such things as the aorta of the sand boa constrictor, the spleen of the African lion, the rumen contents of the onyx, or the uterus of the agouti will now know where to apply.

New Look for Classics

"An Approach through Classics" is a report prepared for the Schools Council on a possible course in the humanities for children between 11 and 14. In these three years, the children are to be given an account of events, myths, discoveries, literature, art, politics and personalities from the Egyptians and Sumerians to the Renaissance. Those who jib at the superficiality of learning implied by this syllabus could well reflect on how few "educated" people could give an account that was more than superficial on any topic within this huge range. What most people learn vaguely and by diffusion it is proposed to teach rather less vaguely, though necessarily with very little detail. But it is, perhaps, a pity that the syllabus makes no mention of any specialization, not because it would be good to induce in children the notion that human development has been a series of "set periods", but so as to point the dangers of generalization which such a course is prone to.

The course involves no study of any particular language nor—a more serious omission—any teaching of elementary linguistics. No one could expect fourteen year olds to have enough Latin to be useful in understanding Roman life, but it might well have been profitable to make mention of language as a repository of culture. The use of translations in the study of classical literature, much emphasized in the report, will also bring problems. "Pupils very soon absorb Homeric style and diction, his similes, stock epithets, etc."—but is it useful to have children emulate cliches, even Homeric ones? The report quotes a splendid

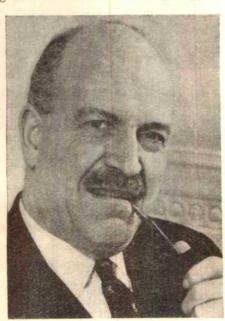

pastiche of nineteenth century Homeric translation,

written by a boy of eleven.

These are, however, minor points. Perhaps the most serious difficulty that would arise if the syllabus came into wide service would be the shortage of teachers knowledgeable enough to take the course.

New Man for Porton

In March 1968, Mr Gordon Neville Gadsby will take over as director of the Chemical Defence Experimental Establishment at Porton, near Salisbury. He will succeed Mr E. E. Haddon, who is retiring. Mr Gadsby, who is the present deputy chief scientist (Army), was an honours graduate in chemistry and a Cadbury Prize winner at Birmingham University and before the war was senior chemistry master at Waverley High School in Birmingham. After service in the Army and as a lecturer at the Royal Military College of Science, he moved into operational research. In 1960 he became director of operational science and research and, later, director of the Army Operational Research Establishment. In 1965 he became director of biological and chemical defence (Army).

Despite its fearsome image, the establishment at Porton is responsible for a great deal of useful work. Mr Gadsby is not yet ready to suggest any changes which he may favour when he becomes director, but makes it clear that he does not want to give the impression of being a new broom.

Improving Traffic Flow

TRAFFIC delays throughout Britain are estimated to cost £750 million a year. This figure is clearly one reason why the Road Research Laboratory is spending £0.5 million on a large scale experiment in traffic control by computer. The experiment, taking place in Glasgow, is described in a recent report from the laboratory.

A similar experiment carried out in West London was devised to solve a particular problem, but the Glasgow experiment is designed to test and compare

eight different systems of traffic control. The experiment started on May 10, and results so far are said to be encouraging. The experiment is controlled by a Marconi Myriad computer which has been used to link 80 traffic signals controlling a square mile in the centre of Glasgow. The systems under test do a variety of things, from minimizing the delay in networks controlled by fixed time signals to arranging for equal saturation on all branches of a crossroad. Each system is assessed by measuring the average journey time over standard routes with instrumented cars. Five of the systems under test have been tried previously, either in this country, Europe or the United States; the other three have been newly devised. As far as the RRL knows, this is the first time that a fully comparative experiment has been conducted. Traffic delays in central Glasgow, the RRL estimates, cost £2 million a year-if only 5 per cent of this can be saved, a reasonable estimate, the experiment would pay for itself in five years.

Following Parasites

The Ministry of Overseas Development has made a grant of £45,000 to establish a new headquarters for what is called—somewhat alarmingly—the Blood Meals Service. This is a unit financed by the government to analyse the stomach contents of blood-sucking insects carrying malarial and other parasites. Smears of the stomach contents are sent from abroad, and their analysis provides clues to the feeding habits of vectors, and other information of importance to foreign workers and authorities such as the World Health Organization. Until now this has been done at the Lister Institute of Preventive Medicine, Elstree, but work has now begun on the new centre at Silwood Park, near Ascot, the field station of Imperial College, and it is hoped that the service will be able to move there early next year.

The Ministry's grant also covers the cost of the service for the next three years, and the new director of the unit, Mr Peter Boreham, is hoping to be able to carry out research on the pathogenesis of trypanosomiasis as well as operating and improving the service itself. The unit will be an important addition to the research teams at Silwood under the direction of Professor T. R. E. Southwood. The Blood Meals Service was founded in 1948 by Professor Bernard Weitz, who continued as director until this September, when he left to direct the National Institute for Research in Dairying at Shinfield, Berkshire.

European Forestry

Forestry cannot keep pace with the marked growth of industrial production. This is one of the important findings of a report called *Cost Studies in European Forestry*, published by the Royal College of Forestry in Stockholm.

Conditions in forests and forest industries are considered in detail for each country, and the results include the share of forestry in the gross national Product, total roundwood balances, external trade in forest products and wage development. Data for Sweden served as a standard for the work in other countries and analysis of material was carried out at the Royal College of Forestry in Sweden. For the purpose of the study, Austria, Finland, Norway and

Sweden were considered to be timber exporting countries, while Denmark, Germany and Switzerland were classified as timber producing and timber importing countries. Britain was considered to be the sole

timber importer.

The report shows that the share of forestry in the gross national product between 1953 and 1962 was highest for Sweden and Finland, but that a declining trend is evident everywhere. Despite this, net production value of forestry in absolute figures has remained approximately constant. In some cases, declining timber prices have been compensated by increased timber output. Germany is the largest consumer of forest products and in 1960 use of forest products in Britain amounted to only half the consumption in Germany. Wood consumption per head has increased in Sweden, Austria, Germany and Switzerland and decreased for Finland and Norway.

One of the most important purposes of the study was to compare the prices of roundwood in the different countries, because these prices determine the revenue which the forest owners receive from timber sales: the distance which the saw logs have to be transported to the consuming centres seems to have a decisive influence. Prices for saw logs are highest in Switzerland and the highest prices for pulpwood are also paid in

Switzerland.

Administrative or overhead costs in forestry are highest in Germany and lowest in Norwegian crown forests. And the report suggests that a systematic levelling of the standard of living of the workers is taking place. Finally, the report concludes that Switzerland makes the biggest profits from forestry.

MRC Appointment

SIR HAROLD HIMSWORTH, who has been secretary of the Medical Research Council since 1949, is to retire at the end of September or earlier. His successor will be Dr J. A. B. Gray. When Dr Gray, previously professor of physiology at University College, London, was appointed second secretary of the council in May 1966, it was widely understood that he would succeed Sir Harold.

Sir Harold Himsworth became secretary at the age of 44. After a distinguished academic career, also at University College, he was appointed professor of medicine at London University and director of the University College Medical Unit. He was knighted in 1952 and elected to the Royal Society in 1955. Under his aegis the budget of the MRC has grown from £1.6 million in 1949 to £14.2 million in 1967–68. During the same period, the number of staff has increased from 1,401 to 3,529.

Parliament in Britain

Nuclear Stations

The Minister of Technology, Mr A. Wedgwood Benn, put the total expenditure on the development of the Magnox system for civil use at about £20 million, just over half relating to the development of fuel elements, in respect of which appropriate surcharges were included in fuel prices. If charges were imposed, sufficient when discounted to 1967 to cover the remaining cost of development of the reactor system itself, the average cost of generation from Magnox stations

would rise by about 0.007d. per unit, assuming 20 years' life and 75 per cent load factors. The expenditure to March 31, 1967, on the development of the Advanced Gas-Cooled Reactor system amounted to £89 million. Whether a royalty of 0.014d. per unit would recover these costs in full depended on how many such stations were built and how much electricity they generated. (Written answers, December 11 and 12.)

Students

MRS S. WILLIAMS, Minister of State, Department of Education and Science, estimated that the annual cost to public funds of a student who completed his course at a college of education was about £785, and that the estimated annual cost to the Exchequer was about £510. Non-graduate entrants to courses of initial teacher training numbered 29,058 in 1965 and 33,378 in 1966; the provisional figure for 1967 Most of these students are following was 36,500. 3 year courses; of the students who entered in 1961, 1962 and 1963, about 90 per cent completed their courses satisfactorily. About 4 per cent of entrants did not continue in training beyond the first year For 1966-67 the technical colleges of the course. admitted to advanced courses some 27,000 full time and sandwich students, 36,000 part-time day and 28,000 "evenings only" students. It is estimated that in the academic year 1971-72 total recurrent expenditure by universities (other than expenditure on research contracts and other self-balancing items and local authority rates) will be about £200 million with student numbers between 220,000 and 225,000, giving an average expenditure per full-time student of about £925, compared with £835 in the academic year 1966-67. The fourth annual report of the Universities Central Council on Admissions gives a total of 13,535 admissions by universities in Great Britain to first degree and first diploma courses in pure science starting in October 1966, and estimates that places could have been found for about another 1,000 if more suitably qualified candidates had come forward. (Written answer, December 14.)

Oceanography

In an adjournment debate in the House of Commons on December 11, Mr T. Dalyell raised questions about the development of the marine sciences and environment and the general state of British oceanography. Replying for the Government, the joint Parliamentary Secretary, Minister of Technology, Dr J. Bray, concentrated on the technological rather than the scientific aspects. The integration of the Ministry of Aviation with the Ministry of Technology had facilitated the combination of those parts of the defence research problem and the civil research programme which fall Following the Harwell Conference a in this field. working party had been asked first to review research and development in progress on all aspects of marine science and technology in the United Kingdom, and secondly, to identify areas of marine science and technology which are likely to be the most profitable economically and to consider what further research and development would be necessary to exploit them. Thirdly, the working party was asked to advise on a programme of action and on means of co-ordinating the existing and proposed programmes of research and development.

NEWS AND VIEWS

Seal Hunting

In her article on page 1237, Mrs E. G. Simpson describes the efficient way in which, under United States administration, the Fur Seal of the Pribilof Islands, Alaska, is hunted and killed. These observations are a happier story than the previous report (Nature, 214, 1274; 1967) of the killing of the Harp Seal in the Gulf of St. Lawrence, when Mrs Simpson concluded that "a large percentage of the hunted animals die in a manner which is of doubtful humanity". At the Pribilof Islands the United States government is itself responsible for the killing of seals, whereas in the Gulf of St. Lawrence the hunting of seals is the prerogative of commercial organizations which are supervised, as far as possible, by government inspectors.

Humanitarian issues apart, the ecology of the two seal populations is also affected by the different government policies. At the Pribilof Islands, the stock of the Fur Seal has grown from an overhunted population of about 200,000 at the beginning of the century to its present value of one million. This seems to be the optimum population size, above which the natural mortality rate rises. The control and exploitation of the Fur Seal is recognized as a classic example of how an animal population may be conserved with maximum economic value and minimum ecological damage. In contrast, the Harp Seal population of the Gulf of St. Lawrence is under no such rigorous control. Its numbers are estimated to have fallen from about 3 million in 1950 to 1 million ten years later. Since 1965 the Canadian Government has fixed a quota of 50,000 on the number of young seals which may be taken in each year. This applies only to firms operating from ships and aircraft, and Mrs Simpson estimates that a further 30,000 seals may be taken by firms operating from the land. The Canadian Department of Fisheries has carried out population surveys and believes that at its present numbers the Harp Seal is in no danger of extinction. But the level at which an animal population ceases to be self-sustaining is difficult to determine, and not all zoologists share the Canadian Government's optimism. The USSR, for example, has prohibited the hunting of the Harp Seal in the White Sea since 1930, when numbers had declined to dangerously low levels.

The argument is often put forward, both by seal hunters and fisheries, that because seals are voracious predators of fish, the severe culling of their numbers enables fish populations to increase so that more fish can be caught. There is no evidence, however, that seals materially affect the stocks of fish in the sea, which are subject to large fluctuations caused by several factors of which the size of the seal population is only one. Harp Seals are also vectors of the codworm nematode in one stage of its life cycle, but here again the infor-

mation upon which an assessment of economic damage might be made is not forthcoming.

In fairness to the Canadian Government it should perhaps be emphasized that the hunting of the Harp Seal is much more difficult to control than that of the Fur Seal in the Pribilofs. Only the young Harp Seal, the fur of which is still white, has economic value, although a small but unrestricted number of adult pelts are also taken for leather. The young seals are distributed over a large area of the ice and cannot be herded together as can the bachelor males of the Fur Seal. But under these circumstances, it might be argued, ecological studies should have been seen to be all the more necessary.

Chromosome Deletion in Action

A TEAM under the leadership of Professor W. M. Davidson of King's College Hospital, London, has produced what may be the first pictures of somatic autosomal deletion in man not induced by mutagens. viruses or irradiation. (Day, E. J., Marshall, R., MacDonald, P. A. C., and Davidson, W. M., The Lancet (i), 1307; 1967.) A child was admitted to hospital with multiple somatic anomalies and died within three months. Lymphocyte cultures from both father and child showed partial deletion of the long arm of chromosome 18, the mother's karyotype being normal. Both father and mother are phenotypically normal, so that it is to be expected that the father has a balanced translocation, though no normally large chromosomes could be detected. At the same time one fifth of the cells of the father's lymphocyte culture showed progressive fragmentation of the short arm of chromosome This chromosome is known to be polymorphic. the sizes of its arms varying between individuals and even in the same tissues of the same individual, but fragmentation of this kind has not previously been noted. The extent of the abnormality varied from cell to cell in such a way as to suggest that deletion was in process of developing.

The team hints at the possibility that some process which first affected chromosome 18 may now be starting to act on chromosome 16. It is also possible that the abnormality is hereditary, but there is as yet no evidence to support this. The team is now working on cell cultures of the skin of the father. If chromosome 16 is found to be normal in these and other cultures of the father's tissue, then it is unlikely that the man inherited the defect from his parents; the hypothesis that the chromosome fragmentation in the lymphocyte culture represents the beginning of deletion will therefore be greatly strengthened.

Stellar Diameters Observed

The first results have now been published (Monthly Notices of the Royal Astronomical Society, 137, No. 4: 1967) of the measurements of stellar diameters carried

out with the apparatus constructed by Dr R. Hanbury Brown and his colleagues. The intention is to correlate in time the intensities of the light signals received at two mirrors separated by a distance of some tens of metres. Hanbury Brown and Twiss first showed in 1956 that such a correlation should exist between two coherent beams of light, but the realization of their plans has been an arduous undertaking. The construction at Narrabri Observatory, 300 miles north of Sydney, consists of a circular railway track 188 metres in diameter on which are mounted two composite mirrors 6.5 metres in diameter. Time correlations are based on periods of observation which may amount to more than 40 hours. So far, the apparatus has been used to measure the diameters of fifteen stars, most of them young O and B stars. Angular diameters of about one-thousandth of a second of arc have been obtained in this way. One valuable by-product of the work so far is a more accurate estimate of some surface temperatures.

Keep on the Grass

by Mary Lindley

THREE members of the Nuffield Unit of Tropical Animal Ecology described some of their work in the Queen Elizabeth Park—which surrounds Lake Edward and Lake George in western Uganda—on the habits of the larger mammals at the scientific meeting of the Zoological Society of London on December 12.

Mr C. Field of the school of agriculture in Cambridge has studied grazing habits using wild and tame animals. The hippopotamus which grazes at night and spends the day in the water has caused some serious erosion, and cropping began in 1958. About 10,000 animals have been shot since then with the aim of reaching an optimum density of twenty hippos to a square mile. Mr Field has been able to make use of this cropping programme to examine stomach contents, and in four years he examined between two and three thousand hippos. The preferences of the animals were found by identifying the inflorescences in their mouths as they grazed. Mr Field also had tame animals, like the buffalo in the photograph, which were taken into the field and watched while they grazed.

The first results of this work have shown that the hippo prefers the creeping grasses, that the antelope prefers the more erect cauline leaf grasses and that the buffalo prefers the tussock grasses. Leaves of the cauline species have a high protein content, but the buffalo has a large mouth and cannot separate them from the stems. The antelope, however, can separate the stem and leaves and will eat these grasses. The hippo is the dominant species and it acts as a nutrient sink by grazing heavily and defecating into the water. Heavy fishing means that these nutrients are lost to the environment. Hence the need for cropping, and there are signs that the same may have to be done to the elephants, which are increasing very rapidly.

Mr C. Spinach of the Wellcome Institute of Comparative Physiology has been studying the waterbuck, and he discussed some aspects of its territoriality and socialization. The male is weaned at six to eight months and joins a bachelor herd, usually about seven animals. At five or six, the bachelor settles down to establish a territory and by seven years is

completely territorial, occupying a territory from which he is unlikely to wander and which he will vigorously defend. The territories observed by Mr Spinach varied in size from 40 to 550 acres. The waterbuck may establish himself by joining an already established male in his territory, being allowed to stay if he holds his own in battle. A weak male may return to the herd and later establish his own small territory. Mr Spinach watched a male do this, and later return to the territory of his original choice when the established male was beginning to age. The average maximum life span is about eleven years, but at nine to ten years a male may be driven into an inferior territory, perhaps without water. This may in part account for the peak in deaths at this age.

Observing the feeding habits of a tame buffalo in the Queen Elizabeth Park, Uganda.

The female waterbuck wander through a home range which covers several male territories, but with increasing age she restricts herself more. She gives birth in isolation within the male's territory. Territoriality seems to ensure the maximum of reproduction with the minimum of aggressive contact, but Mr Spinach remarked that much more information is needed before the full reasons for territoriality are understood.

Mr J. Grimsdell of the Marshall Laboratories in Cambridge has studied the African buffalo, which is abundant in the lake regions of western Uganda. In Queen Elizabeth Park there are more than 16,000 buffalo in herds usually consisting of between twenty and forty animals. Members rarely leave the herd, in which there is linear ranking. Rank is related primarily to seniority; the number one bull is one of the oldest but not necessarily the oldest. Each animal appears to know its place in the ranking and there is little fighting.

Mating is carried out by the higher ranking bulls, and the peaks in conception and births, which follow after eleven months of gestation, occur towards the end of the rains. This is a time when the protein content of the grass is near the maximum. This seems to be a solution to the problem of providing extra nutritional requirements for the near term female and the newborn buffalo. Areas such as the Queen Elizabeth Park may soon have to pay their way, and the buffalo, if efficiently managed, could be a good source

of meat. With the buffaloes, as with the other animals, the Nuffield Unit, although engaged in a pure research project, is providing information which will be valuable to the management of the park in their work.

Inhibitor Inhibited

from our Molecular Biology Correspondent

THE trypsin inhibitors form an interesting class of low-molecular weight proteins of remarkable specificity. Several plant and animal trypsin inhibitors have been studied, and quite recently the full amino-acid sequence of the bovine pancreatic inhibitor (often known as Kunitz and Northrop's basic inhibitor) has been determined. Like other animal trypsin inhibitors, this protein has three disulphide bonds, and their relation to the reaction with trypsin has been investigated by Kress and M. Laskowski, sen. (J. Biol. Chem., 242, 4925; 1967).

The sequence and position of the disulphide bonds were both reported earlier by Laskowski and his group. It now turns out that one of the disulphide bonds (between residues 14 and 38) can be reduced without damage to the other two—a reaction which has been paralleled in several other proteins. Again, as in one or two of these cases, the product retains its activity. If, however, the new sulphydryl groups are carboxymethylated, activity is lost and, indeed, the protein becomes prone to hydrolysis by trypsin. The partially reduced inactivator reforms the broken disulphide bond under the usual conditions of reoxidation in air; in its complexes with trypsin, however, the reoxidation is almost wholly prevented.

The drastic effect produced by the quite modest steric disturbance of introducing the two carboxymethyl groups is in interesting contrast to the observation of Chauvet and Acher (J. Biol. Chem., 242, 4247; 1967) that the four lysines of the inhibitor may be guanidinated without detriment to the activity. This reaction amounts to a small displacement of the charge by effectively lengthening the lysine side chain. The overall charge, however, must be maintained, for acetylation of the lysines inactivates the inhibitor completely. It is also interesting to note that whereas all five amino groups (the four lysines and the N-terminus) are reactive in the free state, one of them (lysine-15) is shielded in the complex with trypsin, and may therefore form part of the active site.

Both trypsin and the inhibitor are quite small molecules; the latter indeed has only 58 residues, and is therefore one of the smallest globular proteins (excluding from this definition the polypeptide antibiotics). This therefore provides one of the very simplest systems available for the study of specific interactions between proteins.

Histone Synthesis in HeLa Cells

from our Cell Biology Correspondent

THE discovery that histones are uniquely associated with DNA in cell nuclei and do not occur in the cytoplasm provoked the hypothesis that histones function as repressors of gene transcription and has led to attempts to establish a temporal relationship between histone and DNA synthesis. It now seems fairly certain that histones do have a role in genetic regulation, but whether DNA replication and histone synthe-

sis are always synchronous is still an open question. No doubt much of the confusion about this relationship has arisen because different workers have used different methods to identify histones and synchronize cell populations and they have used different cell types. But Robbins and Borum (*Proc. US Nat. Acad. Sci.*, 57, 409; 1967) and Borum, Scharff and Robbins (*ibid.*, 58, 1977; 1967) seem to have established that, in HeLa cells at least, histone and DNA synthesis are synchronous and, more unexpectedly, that histones are synthesized in the cytoplasm.

Robbins and Borum used gel electrophoresis to identify two heterogeneous histone fractions in protein extracted from a synchronized population of HeLa cells with hydrochloric acid. With this method and using C^{14} lysine to label histones and C^{14} thymidine to label DNA, they found that lysine incorporation into histone is negligible during the G_1 phase of the cell cycle. But as the S phase begins and DNA synthesis starts, lysine incorporation into histones increases. The incorporation of lysine into non-histone protein stays constant, however. Thus the synthesis of histones is uniquely synchronized with DNA synthesis.

Where are the histones synthesized? To answer this, synchronized cells were given a 2 minute pulse of C¹⁴ tryptophan, to label non-histone protein and H³ lysine, and then chased in a medium containing a large excess of unlabelled lysine and tryptophan. After 2 minutes incorporation, 80 per cent of the lysine was in the cytoplasm and during a 2–12 minute chase the amount of incorporated lysine in the nucleus increases by 33 per cent. Lysine rich protein is therefore being transported into the nucleus. Tryptophan labelled protein, however, shows no such transfer. The clear implication is that the histones are synthesized in cytoplasm, and if so it should be possible to detect cytoplasmic polysomes synthesizing histone.

Robbins and Borum analysed the distribution of incorporated lysine and tryptophan among HeLa polysomes from cells at G_1 and S phases. At the S phase in the cell cycle more small polysomes are present than at G_1 and a significantly greater percentage of the lysine is associated with the small polysomes than with large polysomes. Furthermore, when cytosine arabinose, an inhibitor which stops DNA and histone synthesis, is given during the S phase, the lysine rich small polysomes disappear. They concluded that DNA and histone synthesis is synchronized and that the histones are made in the cytoplasm on small polysomes.

Borum, Scharff and Robbins, continuing the study, isolated the nascent polypeptides from the small cytoplasmic polysome fraction and found that they are lysine rich and migrate on gel electrophoresis like authentic histones from nuclei. A rapidly labelled RNA fraction isolated from the polysomes appears to be histone mRNA. This RNA first appears at the beginning of the S phase and its synthesis ceases about 2 hours before cell histone synthesis ceases at the end of the S phase. The histone mRNA has a short half life of 1-1.5 hours.

These results indicate that the principal control of histone synthesis is at the level of gene transcription, but this does not, of course, exclude some fine control at the translational level. It will be very interesting to see whether or not all these conclusions are valid for other cell types.

Thin-layer Chromatography

by
E. J. SHELLARD
Chelsea College of Science and Technology,

A symposium on quantitative thin-layer and paper chromatography will be held on January 3 and 4, 1968, by the Pharmacological Society of Great Britain and the Society for Analytical Chemistry. What follows is a description of how this new technique has been developed in recent years.

In 1903, the Russian botanist, M. Tswett¹, working in Warsaw, separated the various components of chlorophyll by pouring a light petroleum extract of green leaves over calcium carbonate packed in a long glass tube and followed this by adding more of the solvent until he could see the different coloured bands separated in the column. Tswett named this technique "chromatography", but his work remained unnoticed until the early 1930s when the technique was used to separate the components of many complex mixtures, particularly pharmaceutical preparations, so that similar preparations could be distinguished. This was followed by the separation of mixtures of chemical substances, some of which were colourless so that special methods for detecting the substances after separation had to be devised. Since then there have been many and sometimes dramatic advances in methods of chromatographic separation so that the original definition of chromatography no longer applies.

Today, chromatography may be defined as those processes which permit resolution of mixtures by effecting separation of some or all of their components in concentration zones or in phases different from those in which they were initially present, irrespective of the nature of the force or forces causing the substances to move from

one phase to another.

Kinds of Chromatography

The scientific principles involved in chromatographic separation may be adsorption, partition or ion exchange, and gel filtration could also be included in the wider concept of chromatography. In any particular separation one, two or all of the first three processes may be involved although for historical reasons the names given to the various methods are based on the actual technique rather than the scientific principles involved—for example, column chromatography, paper chromatography and gas

chromatography.

The most recent development is thin-layer chromatography (TLC) which involves the use of a thin layer of a powdered stationary phase spread evenly over the surface of a suitable support such as a glass plate. The earliest attempts to use this "open column" method were made by two other Russian workers, Ismailov and Schraiber², in 1938, but little was done to exploit this technique because of the problems associated with loose powder and the difficulties of detecting colourless components. Meinhard and Hall³ in 1949 overcame the difficulties to some extent by mixing the powdered adsorbent with starch paste in order to make the material adhere to the plate. Others tried different binding agents, but it was not until 1956, when Dr Egon Stahl^{4,5}, professor of pharmacognosy, University of Saarbrücken, published details of standardized stationary phases, equipment and techniques which allowed more reproducible results, that thin-layer chromatography became a widely used separation technique.

Alumina and Silica Gel

In 1956 the stationary phases commonly used were activated aluminas and silica gel so that the separation was essentially by adsorption. As such, the technique was claimed to have many advantages over paper chromatography, particularly for hydrophobic substances, though the method could be used with advantage for hydrophilic substances. Today magnesium silicate, cellulose, ion exchange celluloses, impregnated kieselguhr, powdered nylon (polyamides) and gel filtration materials are also used so that all the four physico-chemical processes may be involved and the method is equally applicable to both hydrophobic and hydrophilic substances.

The original claims for the advantages of TLC over paper chromatography are fully justified. They are: (1) greater efficiency; (2) greater sensitivity; (3) greater speed; (4) more compact spots; and (5) the possibility of using more corrosive agents and higher temperatures for detecting the substances. TLC is much more selective because complete separation of very closely related compounds with only slight differences in structure or con-

figuration can be achieved.

The advantages of TLC over gas chromatography lie in the simplicity, cheapness and resolving power at room temperature so that it can be used for high melting point

substances without difficulty.

There are many variations in the design of equipment available for TLC, but the original and basic technique described by Stahl is as follows. Thin layers, 250-300µ thick, of a suitable adsorbent* are prepared by spreading thick aqueous suspensions of the adsorbent over the surface of glass plates which are then air dried to remove excess water and finally heated for a definite time at a given temperature. This is essential if adsorption is the main process for separation. The mixture of components to be resolved is applied in a suitable solvent as small spots 1 cm (or more) apart along a starting line 1.5 cm from one edge of the plate. The plate is then carefully placed in a separating chamber or tank containing sufficient solvent so that the plate stands to a depth of 0.5-1.0 cm and the tank is then closed with an airtight lid. The solvent rises by capillary action through the layer on the plate to a predetermined height (usually 10 cm), after which the plate is taken from the tank, the solvent removed by means of warm air and the plate examined for the positions of the separated substances. If the substances are colourless, examination in screened ultraviolet light at 254 mu and 365 mu may be useful, but

• The materials are referred to as "adsorbents" in the commercial literature, irrespective of the particular process for which they may be used.

it is usually necessary to use a specific spray reagent and possibly to heat the plate as well.

Absorbent Layers

A number of modifications and refinements of this technique can be used. The support for the stationary phase need not be glass, provided it has suitable properties, and the thickness of the layer may be varied from 100 to 500µ; if the thinner layers are used, smaller loads must be applied. The actual amounts which can be applied depend on the degree of resolution of the mixture and the ease with which the separated substances can be detected, but normally the range is 10-100 µg. Lack of uniformity in the thickness of the layers may affect the results, but this can be overcome by using the commercially available spread layers, either on glass or on plastic film (known as precoated plates or foils). Although the earlier adsorbents all contained gypsum as a binding agent, adsorbents and precoated plates and foils can now be obtained without binding agent.

Since the slurry of the stationary phase used for spreading the layers is usually made with an aqueous medium, buffer solutions may be used so that partition takes place at known pH values or other substances may be added which will facilitate separation or detection of the separated compounds. The inclusion of silver nitrate to give an impregnated layer has proved very successful for the separation of liquids, while the inclusion of sodium fluorescein facilitates detection of colourless unsaturated compounds if the developed plate is subsequently exposed to bromine vapour when the fluorescein is converted to eosin except in those parts occupied by the substances. Inorganic phosphors are also added so that substances can be detected by examining the developed plates in screened ultraviolet light of appropriate wavelength, the substances quenching the fluorescence caused by the phosphor.

Measurements of Diffusion

Although the primary use of TLC is to effect separation of mixtures of substances, it is desirable and frequently essential that the Rf values, which are defined as the ratio of the distance moved by the solute to the distance moved by the solvent front, obtained for the separated substances should be reproducible. Many factors are concerned with reproducibility of Rf values in TLC, but the most important is the nature of the stationary phase at the time of use. This involves to some extent the uniformity of the layer thickness-and in this respect the commercially precoated plates and foils may be an advantage-but chiefly the water content of the layer. The water content of the layer and thus the activity of the adsorbent can be preconditioned by the heating process after spreading, but, in order to retain this activity, it is essential that the plates are stored in an atmosphere of earefully controlled humidity until required for use. Dallas⁶, Geiss^{7,8} and others have shown that the variable humidities of different laboratories-or the same laboratory at different times—can affect the adsorptivity very considerably and even the breath of the worker on the layer while he is applying the substance can reduce the adsorptivity of alumina. If the Rf value is not vitally important these elaborate precautions are not necessary, but, even so, the plates should be stored in a desiccator or airtight cabinet until required and should not, even then, be stored for too long a period.

Another factor relating to the layer itself is the amount of binder which might be present. Calcium sulphate is itself a strong adsorbent and it is possible that variations in the amount present can affect the separation. Thus it is better to use adsorbents without binding agents if reproducibility of Rf value is required. Another important factor affecting reproducibility of Rf values is the state of the atmosphere on the tank during development. As with paper chromatography, the atmosphere in the tank should be saturated with the vapours of the solvent being used for the development and the layer, like paper, should be conditioned in this atmosphere before being developed. Unfortunately, the majority of commercially available tanks are not designed for this, and the only effective way of ensuring saturation is to line the inner sides of the tank with filter paper soaked in the solvent system. It might be noted, however, that the actual resolution of mixtures is frequently better in tanks that are not fully saturated.

Choice of Solvents

Separation of a mixture may not be complete after a 10 cm movement of the solvent, in which case the distance can be increased to 12 or 15 cm or modified techniques such as two-dimensional, multiple and gradient development or electrophoresis in association with TLC can be used. Reversed phase TLC can be employed by impregnating an adsorbent with a non-polar substance-for example, liquid paraffin—and selecting a suitable solvent system for development, while low temperature and gradient TLC are also modifications which have been used to bring about separation.

The choice of solvent system will depend on the nature of the stationary phase and on the type of substances that need separating. Several workers have indicated eluotropic series suitable for adsorption chromatography (starting with light petroleum or hexane as the nonpolar solvent and ending the series with methanol as the most polar solvent). With polyamides the eluotropic series starts with water and moves through ethyl acetate to less polar solvents. It may be necessary to use a mixture of two or more solvents to effect a good separation, but with adsorption chromatography a mixture of solvents may behave as independent solvents to give two or more solvent fronts and this would affect the movement of the substances. The solvents used in TLC should always be freed from impurities. Stahl's recommends that all solvents should be purified by distillation before being used.

The methods of detecting substances after separation are basically the same as those used for paper chromatography. As indicated previously, however, more corrosive substances, including sulphuric acid, can be used with the inorganic adsorbents. Sulphuric acid followed by heating which chars the organic substance to give brown spots is not specific, but there are many specific reagents available; for example, ferric chloride in perchloric acid followed by heating at 150° C for half an hour is specific for certain oxindole alkaloids but is unsuitable for paper chromato-

Recording Results

The method of recording results needs to be discussed because it is not convenient to keep the layer adhering to the glass plate in the same way as it is possible to keep paper chromatograms. If the Rf value is reliable this can be given together with details of the shape, colour, etc., of the spot. Otherwise a permanent record should be made, such as a photograph, tracing, etc. It is also possible to preserve the actual layer by spraying it with a solution of polyvinylpropionate which sets to a clear plastic film and which, together with the adhering layer, can easily be stripped from the glass plate under water. Precoated foils provide permanent chromatograms.

It is understandable that the separation of the components of a mixture by such a relatively simple technique should lead to the possibility of isolating the separated substances on a larger scale. By using larger plates and thicker layers, increased loads can be applied although the degree of resolution is reduced. Thus it is only possible

to use preparative thin-layer chromatography for isolating those compounds with Rf values which are significantly different from those of adjacent compounds when examined on the conventional layers. It is claimed that 500 mg can be applied to a layer 5 mm thick, although it is more common to apply 100 mg as a continuous band to a layer 1 mm thick, because the problems associated with the preparation of a layer 100 × 30 cm and 5 mm thick are very great. The position of the separated bands can be detected either by ultraviolet light or by spraying a narrow strip along each edge of the plate and the zone of adsorbent containing the substance can then be removed from the glass plate and the substance extracted with a suitable solvent. This method has considerable advantage over column chromatography because in order to separate large quantities of material wide columns are necessary with the subsequent loss of efficiency because of the heat of adsorption produced in the middle of the column.

Quantitative Methods

It was also inevitable that the separation of the components of a mixture by the technique should lead to the possibility of estimating the amount of substance present. As in paper chromatography, there are two possible procedures (after separation and detection). procedure is the determination of the quantity of substance after eluting the substance from the layer. requires a quantitative recovery of the substance from the adsorbent without the extraction of interfering substances. This latter condition is rarely achieved, however, and it is necessary to extract a similar amount of adsorbent taken from the same plate at a corresponding Rf value to use as a reference solution.

The second procedure is the determination of the quantity of substance directly on the layer. This presents a number of problems, not the least of which is the determination of the exact boundary of the spot and to distinguish it sufficiently from the adsorbent. This may The earliest be achieved by a suitable spray reagent. quantitative procedures were those by Seher, in 1960,

who plotted area of spot against weight of substance, and this was followed by Purdy and Truter10,11 in 1962, who established a linear relationship between the square root of the spot area and the logarithm of the weight of substance. A method of minimum spot visibility has also been devised whereby the substance is progressively diluted and chromatographed until no spot is visible, the results being compared with similar dilutions of a known quantity of the substance. The intensity of colour in spots, whether naturally coloured or as a result of spray reagents, can be measured with a densitometer and the method can be extended to the measurement of fluorescence or the quenching of fluorescence. (Spots which are radioactive may be quantitatively assessed by specially designed radio scanners.) Recently Stahl and Jork 12 have developed an ultraviolet spectrophotometer which can measure ultraviolet adsorption of the substance directly on the plates.

There is no doubt that TLC has developed very considerably during the 10 years or so that have elapsed since Stahl renewed interest in this very simple technique, and it must be one of the most commonly used separation techniques used today. It finds application in all branches of chemistry, in biochemistry, pharmacognosy and pharmacology, to name but a few of the sciences which have benefited considerably from the ability to separate and determine minute quantities of substances in admixture.

Long term (chronic) pollution can drastically reduce both the floristic diversity and the net annual primary production of littoral and sublittoral ecosystems dominated by attached macrophytes¹.

Pollution from oil and detergent deposited on the beaches of Devon and Cornwall after the grounding of the Torrey Canyon on March 18, 1967, has altered the balance of littoral and sublittoral ecosystems at two sites. This effect is most marked on the littoral zone, and falls off below the low water mark.

> The Torrey Canyon disaster presented the opportunity of assessing the effects of short term (acute) pollution by crude oil and detergent. A phytosociological survey at twenty-nine sites along the coasts of Devon and Cornwall

in September 1966, by one of us (D. M. J.), gave a reference point for the post-disaster study.

Peak cropping methods used in the study of the primary production of kelp forest ecosystems have proved to be useful in comparative studies of the performance of species and species groups within such ecosystems in relation to the whole environment^{1,2}. Comparative studies of polluted and non-polluted ecosystems of this type within the disaster area should give corroborative evidence of damage if it has occurred.

All sites which had been surveyed in September 1966 were re-surveyed by exactly the same methods (those of the Zurich Montpellier school³) during the latter part of August 1967, some 5 months after the principal period of pollution by oil and detergent. The results are summarized in Tables 1 and 2.

Table 1 shows comparable phytosociological data for the littoral zones of eight sites. Cover values for the dominant species only are presented. The first figure in each case gives the cover value for the species for the whole littoral zone, the second is the highest cover value recorded for that species in any quarter square metre on the shore. Perhaps the most significant figures are those for the percentage of the rock surface between mean high water surface (MHWS) and mean low water surface (MLWS), which was devoid of attached macrophytes. At two sites, Sennen Cove and Porthleven, in August 1967. all stable rock surfaces were completely covered with a mat of green seaweed mainly Enteromorpha compressa4 and E. intestinalis. This is in sharp contrast to the situation at the same sites in 1966, and to the pre- and post-pollution data for all the other sites where the macrophyte cover was between 15 per cent and 70 per cent. Lamorna Cove deserves special mention; this site escaped during the principal phase of pollution, but was oiled and immediately cleaned with detergent in early summer. It is interesting that at this site three of the dominant species have increased in abundance. Inspection of the total phytosociological data (not presented here) shows no differential effect of loss or gain of the rarer species when comparing the polluted with the nonpolluted sites.

Study of the total phytosociological data for the sublittoral ecosystems shows that there has been no change in the cover abundance values for any dominant species. except Saccorhiza polyschides, which has shown a marked reduction at all sites, some far removed from the disaster area. Table 2 summarizes the floristic data for all sublittoral ecosystems studied. The loss and gain of species, all of which are in the category of lowest cover abundance. can be explained by natural loss or recruitment of species in mixed algal populations, or could be a result of the difficulties of sampling experienced by the diving phytosociologist. All that can be concluded from the data is that there has been no drastic effect on the species composition of the sublittoral ecosystems studied and that there appears to be no species which is particularly susceptible to this type of pollution.

At four sites, Roskilly, Hoe Point, Sennen Cove and Porthleven, more accurate studies of the overall cover values of the macrophytes were carried out. Table 3 gives the comparative data obtained from visual estimation of cover in twenty quarter metre square quadrats placed at random on solid rock surfaces at each site. If the very large cover values at both Sennen and Porthleven are attributable to pollution as indicated by the phytosociological data, then the effects of pollution are much less marked even in the immediate sublittoral.

Comparative studies of the structure and performance of kelp forest ecosystems at seven sites were carried out to investigate further any possible effects of pollution in the sublittoral.

Laminaria hyperborea is a perennial algae, the stipe and hapteron growing for several years, a new lamina being produced each year from an intercalary meristems. Growth measurements of the perennial parts can be regarded as an integrated measure of performance in relation to the environment for the life span of the diplophase. Measurement of lamina production can be regarded as an assessment of performance in relation to the environmental conditions of the current growing season.

Table 3. MEAN PERCENTAGE ROCK SURFACE COVERED BY MACROPHYTES

	Unpolluted	Polluted	Polluted littoral zone markedly green			
	Roskilly	Hoe Point	Porthleven	Senner Cove

* Horizontal and ve	rtical rock fa	ices.				

Because of the great variability of the inshore marine environment over very short stretches of coast, it would be impossible to draw conclusions regarding the effect of pollution simply from a direct comparison of lamina performance unless the effect had been drastic. Using stipe performance at each site as a scaler for the effects of natural environmental conditions, it should be possible to arrange the sites in a decreasing order of "kelp potential". If lamina production has not been affected by pollution, then the sites should fall into the same order when arranged on the basis of lamina performance.

In Fig. 1 is shown the mean standing crop of both stipe and lamina plotted against age for kelp forests in shallow water where the greatest effects of pollution might be expected (0-6 m depths) at each site. Arrangement of the sites on the basis of integrated figures either

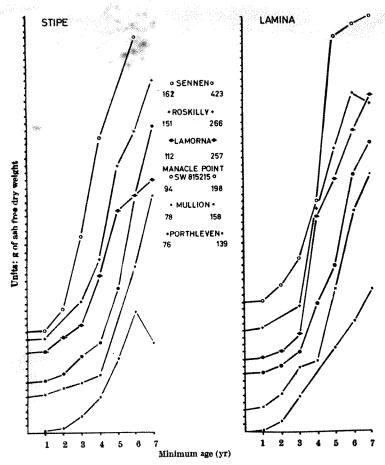

Fig. 1. Mean individual standing crop plotted against age. The origin of each curve is zero for that curve. Units were g of ash free dry weight; for stipe 1 unit = 1 g; for lamina 1 unit = 2 g. The "integrated performance figures" are corrected for this scale difference.

for stipe or for lamina production is the same. The figures which are simply the area beneath the growth curves in each case $\int_0^T w dt$ are shown beside the graphs.

Comparison of the age structure of all kelp forests studied reveals no striking differences between polluted and non-polluted sites except for a much larger number of first year plants at the two polluted sites, Porthleven and Sennen. Table 4 shows the comparative data. It is emphasized that the figures are derived only from the counts made as part of the production studies. They are not large enough to allow statistical treatment; however, the difference noted is so striking that it is felt it should be put on record.

Table 4. MEAN NUMBER OF FIRST YEAR KELP PLANTS/Ma

Depth below low water mark	Porthallow Manacle Rocks	Ros- killy	Mullion	Hoe Point	Lamorna	Porth- leven	Sennen Cove
0-3 m	4	4		4	2	36	28
3-7 m	õ	2	4	0	0	26	14
7-10 m	8		1	1	0		12
10-13 m	4		8	3			2

All the evidence gained from this study indicates that the effect of pollution from the Torrey Canyon disaster has been to alter the balance of littoral and sublittoral ecosystems dominated by attached macrophytes. This effect is most marked on the littoral zone and rapidly falls off with depth below low water mark.

The replacement of the normal littoral dominants by *Enteromorpha* spp. could be explained by alleviation of competition because of a reduction in the vigour of the former at the polluted sites. This seems an unlikely explanation when the low pre-pollution cover values are

taken into consideration. The replacement of these open mixed populations by a closed mat of Enteromorpha, which still harbours all the dominant species present in 1966, could best be explained by a drastic reduction in the populations of grazing organisms. The other possibility, a direct stimulation of the growth of Enteromorpha, seems unlikely. Georges, and O'Sullivan and Richardson', both report very high mortalities of littoral herbivores, especially limpets on shores treated with detergent. Southwards has shown by experiment that on exposed shores the low cover values of littoral macrophytes can be a result of high population densities of Patella. It might therefore be inferred that all sites showing this phenomenon (green sites) were badly affected by detergent. In many cases local enquiry did not clarify the exact details of the "clean up" operations. There is no doubt that the study areas of both Sennen Cove and Porthleven were treated by direct application of detergent at all states of the tide. Detergent was also sprayed on the study zone at Lamorna while the tide was out. The exact period of treatment of the other sites is not at all clear. We do, however, know that the littoral of all sites referred to as polluted was at some stage covered by a thick layer of oil and that detergent was used in the near vicinity.

Corroborative evidence was gained from a study of the 1967 limpet populations. Table 5 gives the results of a census of limpet populations (Patella vulgata, P. intermedia and P. aspera⁹) carried out at six sites. The figures recorded are simply the means derived from counts in twenty quarter metre square quadrats placed randomly within each zone. No limpets were recorded from the littoral zones at either Sennen Cove or Porthleven, in marked contrast to all other sites which had active

populations of limpets in August 1967.

Porth Mear is one of the most northerly sites affected by oil from the Torrey Canyon. Detailed records of the course of pollution and of the "clean up" operations were kept by one of us (T. D.) at this site.

Three adjacent areas of shore showed the full range of the effects of the disaster. Passing from south to north along the inner section of the bay, an overall distance of only 300 m, the first section was unpolluted, the next was oiled but was left to natural processes of cleansing, and the third section was oiled and cleansed with 2,000 gallons of detergent which was applied direct to the shore while the tide was out.

Table 5. LIMPET CENSUS RESULTS

	Porthallow	Ros- killy	Hoe Point SW 532278	Cape Cornwall	Porth- leven	Sennen Cove
Mid-littoral	48 ± 37	92 ± 56	20 ± 4	40 ± 25	* Vert. 0 * Horiz. 0	0
Lower littoral	28 ± 22	28 ± 23	8 ± 7	18 ± 21	• Vert. 0 • Horiz. 0	0

Figures are mean number of limpets/m².
* Rock face.

The littoral zones of the three sectors were studied using all the methods set out above. Sublittoral studies were confined to two areas, that directly below the artificially cleansed sector and that immediately south of the unpolluted sector, because it was felt that dispersion of the detergent could nullify any differential effects over a shorter distance. The results are summarized in Table 6, and it can be readily seen that they back up the findings of the main study in all details. The results also indicate that it might be safe to conclude that all "green shores" were the result of direct application of detergent during

Table 6. PORTH MEAR DATA, GRID, REF. SW 847716

periods of low water, and that all other polluted shores were not subject to high enough concentrations of detergent to produce this effect.

The following hypotheses are advanced to explain the results of these studies. (1) The effect of pollution from the Torrey Canyon disaster has been to alter the balance of ecosystems dominated by attached macrophytes by the destruction of the grazing organisms. (2) This effect is most marked in littoral ecosystems in which the herbivores play an important part in the maintenance of the balance of the primary producers. (3) The effect was caused by detergent or the detergent oil emulsion and not by the oil alone. (This is in marked contrast to the findings of the study of the Tampico wreck area10, where the populations of grazing organisms were decimated, although no detergent was used.) (4) The effect was most drastic at sites where detergent was applied direct to the littoral zone during periods of low water. It seems surprising then that any effect was found in the sublittoral, and it seems even more surprising that it was only found at the three "green sites", Sennen, Porthleven and Porth Mear 3, especially the latter where the volume of detergent used was comparatively small. If the high numbers of sporelings recorded at these sites

are any more than coincidence of quadrats selected, then an explanation for the phenomenon must be sought. It is suggested that the detergent or emulsion flowed down the shore and maintained a high enough concentration at the rock-water interface to do the necessary damage even at a depth of 7 m. This would corroborate the visual evidence of the death of all fauna in a shallow sublittoral gulley at Porthleven¹¹. At sites where detergent was added to oil floating on water dispersion and dilution of the emulsion through the water mass must have been sufficient to reduce its concentrations to levels which might only affect filter feeders or carnivores after concentration through the food chain. (5) If pollution had occurred later in the year (compare Lamorna) when all the algae would be in a more advanced state of development and grazing would have already taken its toll on juvenile stages, the overall effect would not have been so great. (6) There is no long term direct damage to the algae by either oil or detergent.

A brief visit to a number of the sites in October 1967 showed that changes were already taking place. The green carpet at Porthleven was variegated with patches of bare rock each supporting a new colony of limpets. The following limpet counts were obtained: Roskilly, mid-littoral $174 \pm 37/\text{m}^2$; Porth Mear 1, mid-littoral $81 \pm 20/\text{m}^2$; Porth Mear 3, mid-littoral $4 \pm 4/\text{m}^2$; Porthleven, mid-littoral vertical surfaces 0.15/m2; Sennen Cove. no limpets present.

Effect of Humming on Vision

by W. A. H. RUSHTON Physiological Laboratory, University of Cambridge

Humming causes the eye to vibrate and this can produce a stroboscopic effect when a rotating black and white strobe disk is viewed in non-fluctuating light.

THE correct speed of a gramophone turn-table may be checked by viewing a strobe disk illuminated by electric light supplied by the a.c. mains. The strobe disk consists of alternating black and white sectors radiating from the centre of the turn-table, the angle between sectors being such that when the turn-table is rotating at the correct speed each white sector replaces its white neighbour in 0.01 sec. Because in Britain the a.c. produces a fluctuation in illumination 100 times/sec, the white strobe sectors will always be in a fixed position in space when the light is in its bright phase, and in the intermediate position at the dark phase. Thus, when the turn table rotates at the correct speed, the pattern of alternate lighter and darker

sectors will be seen stationary in space; but it will rotate slowly in the same direction as the turn-table (clockwise) if the speed is slightly too fast. So much is well known and

When the disk is viewed in non-fluctuating light (for example, daylight) naturally no strobe pattern is seen, but the observer may produce it by humming loudly. The note to be hummed for a stationary pattern is 100 c/s (bass Ab). If the note hummed is flat the pattern rotates clockwise; if sharp, counter-clockwise. When several observers hum at once, each sees the pattern moving in the direction appropriate to his own hum, independent of what others are humming and seeing.

Obviously humming interacts with vision in some periodic fashion, the period corresponding to the note hummed. This paper concerns the nature of the interaction.

The perception of visual detail results from a train of events. (a) Light is focused as a sharp image on the retina; it enters the foveal cones, is absorbed by the visual pigment contained in their outer segments and nerve signals result. (b) These signals are transmitted (with mutual interaction) so that they finally reach the brain and perception is a consequence of what they do there.

Impairment of Nerve Transmission

Perhaps humming affects, in some periodic manner, the transmission in visual nerves, for example, by interaction with auditory nerve impulses, shaking the nerve connexions in brain or retina, etc. If the nerve signals, on which the sense of brightness depends, fluctuated 100 times/sec because of such interaction, the effect would be as though the light itself were fluctuating in luminance at this frequency and thus we should see the same strobe pattern with humming as with a.c. lighting.

Light does not set up its nerve message instantly; there is a delay (latency) which depends on the light intensity. At moderate illumination a ten-fold increase in the light energy reduces the latency by 10 msec. This can be observed in electroretinograms resulting from light flashes of various intensities, but a more entertaining observation

is the Pulfrich pendulum1.

A pendulum swinging in a vertical plane is viewed binocularly by an observer with a dark glass over one (for example, the left) eye. He soon adapts to the darker view so that he sees nearly equally with both eyes, but the nerve message is set up with greater delay behind the -10 msec if the glass had 10 per cent transdark glassmission. Thus, in judging the momentary position of the pendulum, the unobstructed right eye sees "where it is", the left where it was 10 msec ago. The reader may verify at once that these two lines of sight intersect not in the plane of swing of the pendulum but behind it on the swing to the right, in front on the swing to the left. The pendulum, therefore, appears to execute an elliptical orbit from whose eccentricity (in conjunction with the geometry of viewing) we may measure the latency difference in the two eyes; it is found to be about 10 msec with a 10 per cent transmitting glass2.

We may now apply this result to the stationary strobe pattern produced by humming. In the same way that placing the dark glass before the eye made the sight of the pendulum refer to a moment 10 msec earlier, so with humming (if the appearance of dark sectors is caused by a periodic impact with nerve signals) the interposed dark glass would cause the dimming to refer to a moment 10 msec earlier. Thus reducing the light down to 10 per cent would cause a rotation of the stationary strobe

pattern by one white-to-white spacing.

I closed one eye and with the other looked at the strobe pattern through a photometric wedge of graded absorp tion from near transparency to 10 per cent transmission. I satisfied myself that I could hum sufficiently in tune with the proper note (provided by an oscillator) to keep the strobe pattern fixed. While in this condition I moved the wedge across the eye so as to change the light intensity rapidly back and forth some eight-fold. The pattern should have rotated back and forth nearly from one white sector to the next. But it remained practically stationary and such movement as occurred was clearly caused by slight variations in the pitch of my hum and was not correlated with the movement of the wedge. This makes it certain that humming interacts with vision before the place where latency develops. Category (b) is excluded; we must examine category (a).

Vibration

Because humming acts on the visual system before nerve messages have been developed to the stage recorded

by the electroretinogram, it looks as though it should act by vibrating the eye. In that case external vibration applied to the head should act similarly. I obtained a vibrator and drove it from an electric sine wave generator whose frequency and amplitude were under control. The same strobe pattern was seen in steady light when, instead of humming, the head was vibrated at the same frequency (for example, 100 times/sec). The vibrator acted well when applied to almost any bony part of the head; the cheek bone (zygoma) or chin was convenient. I could get stronger effects with the vibrator than with humming. When the vibrator was judged equal to humming in its effect on vision it also shook the head to about the same extent.

This was measured by attaching a dental impression to a flexible steel foot-rule held in a vice so that only horizontal vibration was permitted. The edge of the steel, close to the mouth, was brightly illuminated and some lun inous specks were observed in a microscope. When the subject bit on the impression and hummed, the horizontal vibration was communicated to the steel strip and the luminous specks were drawn out into luminous lines the length of which could be measured in the micrometer eyepiece of the microscope. Both humming and the equivalent applied vibration gave a peak-to-peak amplitude of 0·15 mm. With this head vibration the strobe pattern was very conspicuous, the hum was loud and, as the reader can verify, the vibration is easily felt with the flat of the hand on the head.

Impairment of Signal Generation

Perhaps humming or vibration affects in some periodic manner the efficiency with which quanta are caught by the cones or the catch turned into nerve signals. instance, if the turn-table rotates at correct speed and the hum or applied vibration is at 101 c/s, the strobe pattern slowly rotates counter-clockwise, bright sectors passing a fixed point once a second. According to the above explanation, as we gaze at the fixed point it will change from bright to dim and back once a second because the white sectors that are passing this point 100 times/sec are falling now in the efficient, now in the inefficient, phase of the 101 c/s vibration. If this is true, an expectation follows. The alternation of black and white produced by the rotating sectors may be presented without movement. It is only necessary to illuminate a white surface by a d.c. light interrupted at its focal point by a rotating sectored disk. With 50/50 on/off ratio at 100 flashes per sec, the white/black alternations of the strobe disk are imitated and with the head vibrating at 101 e/s we should see a 1 per sec fluctuation in brightness-a slow flicker whose temporal contrast should be about equal to the spatial contrast of the strobe pattern. When this expectation was tested, however, no fluctuation whatever could be detected either with humming or with external vibration of considerably greater amplitude. Evidently the fact of black-white alternation is insufficient as explanation; the way in which black replaces white is important.

Retinal Movement

A small front-surface mirror was set in a vertical radial plane just above the strobe disk. When viewed in a.c. lighting the radial strobe pattern could be seen reflected in the mirror, and when the speed of rotation was slightly changed, so that the sectors slowly advanced on the mirror (naturally) the image sectors advanced from behind the mirror to meet them, light meeting light and dark meeting dark. A less commonplace appearance resulted with humming or vibrating the head (viewing now with d.c. lighting). Again the strobe pattern was seen with sectors advancing on the mirror, and again image sectors advanced from behind to meet them, but now they have changed partners. Light sectors meet dark: dark meet light! If with the hum pattern stationary we point to a white sector, in the mirror we are seen pointing to a dark

sector. Wherein lies the asymmetry? There is none in the equipment, so it must lie in the eye.

The central retina is all moving in one direction at any given moment, but the image it receives is not. The disk and its mirror image turn in opposite senses and, when the retina marches with one, it will necessarily march against the other. Evidently the light/dark strobe pattern results from the superposition of rotation of the strobe on vibration of the retina.

Amplitude of Vibration of the Pattern on the Retina

If the head vibration simply translated all components of the eye equally, the movement of the image over the retina would be the same as if the eye was still and the vibration was applied to the turn-table. The head movement measured here was 0.15 mm. If this was applied to an object 85 cm away it would produce a fifty-fold reduction, that is, 3μ on the retina or 36 sec of arc in the visual field. With this vibration the strobe pattern was very conspicuous; a threshold vibration would be perhaps a third as great.

In order to measure more directly what amplitude of vibration made the strobe pattern detectable, the vibration was applied neither to head nor to object, but to a lens between them. The disk was viewed through a combination of two lenses, $+0.5\,\mathrm{D}$ and $-0.5\,\mathrm{D}$, close together so that zero convergence resulted and the disk was seen at its natural distance. One lens was fixed and the other could be vibrated. A displacement of x mm is easily seen to produce a deviation of $x/2,000\,\mathrm{rad}$ because the lens has 2,000 mm focal length.

When the strobe pattern was observed through the vibrating lens it had the same appearance as when vibration was applied to the head instead, except that the pattern was weak or absent along the diameter parallel with the direction of lens vibration. The amplitude was decreased to the point where the strobe pattern could only just be detected at the most favourable place. The amplitude of the lens movement was measured, as before, by viewing luminous specks on the lens surface in a microscope fitted with a micrometer eyepiece. The movement, x, was 0.09 mm giving 9 sec of arc, or 0.8µ on the retina. The distance between the centres of adjacent cones on the central fovea is 3µ; visual acuity is seldom better than 30 sec of arc. Thus the displacement of the image

across the retina is well below the limits of resolution, and in fact humming does nothing to blur the sharp view of a star. Our final question is "If the vibration is too small for detection when the object viewed is stationary, how is its effect so conspicuous when the object is rotating?"

Superposition of Movements

We have seen that the white sectors of the strobe pattern appear when the motion of the disk combines with one phase of vibration, the dark sectors with another phase. What are these phases? To answer this a 4 D lens was placed 500 mm above the turn-table so that a real life-size image was formed 500 mm above the lens. A beam splitter was placed just below this image plane. Thus when the lens was vibrated at proper speed the strobe pattern could be seen in the image planes by transmission or reflexion in the beam splitter. A fine slit was placed in the image plane above, aligned to coincide with the radiating lines of the strobe disk, and above the slit was a photocell which consequently received light either from the white or the black sectors as they rotated below. When the lens was not vibrating, white occupied one half of the cycle and black the other half, as the record Fig. 1(i) shows. The whole tracing occupies a little more than 1 cycle (horizontal) and the bright phase produces an upward deflexion, which lasts half the cycle.

When the lens was vibrating, the strobe pattern was seen reflected in the beam splitter, white and dark sectors slowly passing a thread placed to coincide with the image

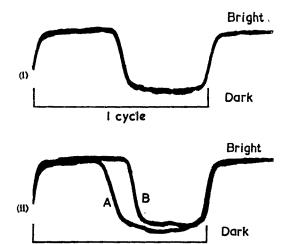

Fig. 1. The rotating strobe disk was focused on to a radial slit which admitted light to a photocell. (i) Photocell output showing one half cycle recording white sector, the other half recording the dark sector, (ii) Records when the focusing lens was vibrating once in a black-white-black cycle. A is when a dark strobe band lay on the slit, B when a bright band lay there.

I cycle

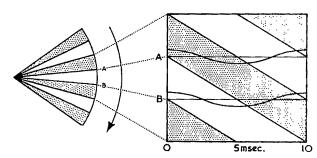

Fig. 2. Diagram to explain results of Fig. 1 (see text).

of the slit seen by reflexion in the beam splitter. Fig. 1(ii) shows two records taken in succession, A at a moment when a dark sector lay on the slit, B when a bright sector lay there. It is plain that in A the upward deflexion occupies less than half the cycle, in B more than half. Consequently the dark bands (A) are where we view an on/off flicker at 100 c/s with the light on less than 50 per cent of the time. This must give an average (Talbot-Plateau) illumination less than (B) where the light is on more than 50 per cent of the time.

Fig. 2 indicates how the records of Fig. 1 arise. At the left is represented the rotating strobe disk (with sector angles drawn four times too large). The vertical at 0 on the square graph represents (at time 0) the position of the rim AB and the adjacent dark segments. As the disk rotates, the white sector AB steadily descends. After 5 msec, A on the disk will have fallen to the initial level of B; after 10 msec the cycle is complete and a new white sector occupies the position AB on the retina. In the absence of vibration, the retinal points A and B remain fixed and follow the horizontal lines which clearly lie half in the white and half in the shade—as in Fig. 1(i). If, on the other hand, the retina is vibrating, retinal points A and B may follow the sinusoidal curves shown. These cause A to lie longer in the shade—as in Fig. 1(ii).

I thank Mr Clive Hood, who improvised much of the equipment and assisted in the observations and the measurements, and I am grateful to the Wellcome Trust for supporting my research.

Research Strategies in Schizophrenia

J. R. SMYTHIES
Department of Psychiatry,
University of Edinburgh

A co-ordinated programme of research into schizophrenia is necessary in Britain.

Ir has recently been demonstrated beyond doubt that there is a genetic factor in schizophrenia in addition to the psychological and environmental factors involved (refs. 1-4 and personal communication from S. S. Kety et al.). This genetic factor must presumably be expressed by means of some biochemical mechanism. It would therefore seem to be a good moment to evaluate the current state of research into the biochemistry of schizophrenia.

The picture is not very bright. A great deal of work has been carried out in the past 50 years with few results. There have been three chief reasons for this: (1) the methodology has often been poor with inadequate controls; (2) the bulk of the work has been carried out in a purely empirical way without any directing hypothesis; (3) insufficient attention has been paid to certain methodological problems peculiar to this field which I shall attempt to outline here.

If we believe that there is a biochemical factor in schizophrenia, then, I would argue, the optimum strategy to follow in research would consist of four stages which must be tackled in order. This same strategy has been followed in the case of depression with notable success. These stages are as follows (with the details filled in for the case of depression).

Stage 1. The discovery of specific chemical agents that can induce the clinical syndrome (or an acceptable model) or alleviate it (for example, reserpine, α-methyl DOPA; monoamine oxidase inhibitors, imipramine). Stage 2. The discovery of the mode of action of these agents on the biochemical mechanisms of the brain (compare the vast literature extant on this subject: the key discovery here was the mode of action of reserpine). Stage 3. Testing the performance of the systems discovered in stage 2 in the patient. Stage 4. Trying to correct any lesion discovered in stage 3.

In depressive illness this programme is well into stage 3 in Edinburgh, Epsom and elsewhere. In schizophrenia research, however, we are still only in stage 1. What is now needed is to break into stage 2. We now have a number of drugs which in certain people produce a psychotic reaction markedly like schizophrenia, but we have very little idea how these drugs work. We also have a number of working hypotheses as to the nature of the biochemical lesion which may be involved in schizophrenia, but these are based only on stage 1 data.

Working Hypotheses

The first working hypothesis was put forward in 1952 by Osmond et al.5, and suggested that an aberration of methylation of catecholamines could lead to the production in the body of hallucinogenic relatives of mescaline. This was based on a comparison between the molecular structure of mescaline and adrenaline (that is, stage 1 data). In the next 5 years two developments occurred. (1) Harley-Mason⁵ had suggested for the first time in the literature that catecholamines might be O-methylated in the human organism: a prediction that adumbrated Axelrod's discovery in 1957 (unpublished work) that catecholamines are normally metabolized by 3-0-methylation by catechol-O-methyl-transferase (COMT). clearly strengthened our 1952 hypothesis, for the lesion postulated now became a small step away from a normal metabolic pathway. (2) Similar hypotheses were subsequently put forward with regard to serotonin and melatonin, both of which are close chemical relatives of hallucinogens (psilocyn and harmine, respectively).

It thus became clear that central transmitters (nor-adrenaline, 5-hydroxytryptamine and dopamine) have a number of psychotomimetic relatives and that the relationship in each case is the same; O- or N-methylation. This led to a complementary and more general hypothesis that schizophrenia is associated with some disorder in trans-methylation mechanisms.

The next stage, lasting from 1962 to the present, consisted chiefly of looking for mescaline-like compounds in the urine. This has still failed to yield conclusive results although most recent evidence suggests that these are various "pink spots", one of which may be tyramine, and another has finally definitely been identified as DMPE (ref. 6), but these may have no direct relevance to the illness. I suggest that a better policy to guide research in the next decade may be the intensive study of the mechanism of action of known chemical agents that can in certain normal individuals induce a psychosis remarkably similar to schizophrenia. The biochemical mechanisms underlying these forms of psychosis may in turn suggest hypotheses as to the type of biochemical lesion that is present in schizophrenia. That is to say, we must carry out stage 2 before we can hope to make any really useful hypotheses in stage 3. The tactics that it would be necessary to follow to carry out this strategy are presented in the form of three interlinked programmes.

Programme 1. When we come to consider how the mode of action of these drugs may be investigated-and why we still know so little in this field-we note at once an important difference between the hallucinogens (and other psychotropic drugs) and the other drugs studied in classical pharmacology. For if we apply the methods of classical biochemistry and biochemical pharmacology to these drugs we may well discover which enzymes, transport mechanisms, metabolic reactions and so on they affect, and details of their own metabolism. But there is no way of telling which (if any) of these properties are related to the effect of the drug on behaviour nor which metabolites are themselves hallucinogenic. In order to determine this we have to repeat these studies using close structural analogues of the drugs in question, some of which are hallucinogenic and some of which are not. Important studies in this field are those of LSD and BOL by the Sandoz group-which showed that the antiserotonin effect of LSD and its capacity for inhibiting cholinesterase are not relevant to its hallucinogenic effect—and the work of Freedman?, who showed that the capacity of LSD for increasing the rate of turnover of serotonin in the brain is so related. Thus the biochemical and pharmacological studies of hallucinogens cannot be properly evaluated without preceding structureactivity relationship (SAR) studies of these drugs and their analogues with respect to their effect on behaviour.

Programme 2. Thus a second programme analysing the interaction of hallucinogens and their analogues with behaviour is necessary. The Sandoz group have carried out extensive SAR work on LSD, but little work has yet been done on the much more interesting compounds mescaline and dimethyltryptamine. It is very difficult these days to give these drugs to humans, and so it has been necessary to develop animal tests that will enable us reliably to detect drugs that are human hallucinogens. These techniques are now available and have been used

in some of the SAR studies suggested^{9,10}. This programme may also be expected to yield new compounds of interest for study in programme 1, such as paramethoxyamphetamine, as well as new agents for exploring the biochemical mechanisms of the brain¹¹. These techniques have, however, additional uses, as follows.

Programme 3. (a) The study of the effect of manipulating brain amines and other brain chemicals on the behavioural effects of these drugs¹², and (b) the promising technique of pretreatment with inactive close structural analogues to see which can inhibit the active drug12. Clearly, here again we have to know which are the inactive analogues. It should be noted again that programme 1 cannot be evaluated, and programme 3b cannot be carried out, without programme 2, and it seems clear that a study in which all three programmes can be carried out in an integrated fashion would be desirable. They would require close collaboration between organic chemists, biochemists, enzymologists, pharmacologists and psychopharmacologists.

Probable Results

What results can be expected from these three interrelated programmes?

- (1) Programme 2 will add to our list of known hallucinogens. Were this all the programmes could do, they would not have much scientific merit and indeed might be less than helpful because hallucinogens are developing into social pests. We have, however, seen that programme 2 is also an essential prerequisite for programmes 1 and 3. Furthermore, the inactive analogues also discovered may be useful in treating addicts and we might avoid the situation of new hallucinogens catching the health authorities by surprise (as in the case of STP). This work might eventually lead to some answers to the problem of misuse of these drugs.
- (2) All these programmes should throw light on the biochemical mechanisms of action of the hallucinogens: programme 1 (+2) directly: programme 3a (+2) on modes of the interaction of hallucinogens and brain amines suggested by clinical data, by their chemical formulae and by Freedman's works; and programme 2 itself by means of possible deductions that could be made from the chemical formulae of active versus inactive hallucinogens, to possible biochemical mechanisms at their site of action. Studies with SAR are often disappointing in this field and it is rarely possible to argue from them directly to the possible molecular configuration of the receptor site, and, indeed, we may be "unable to make answers even to the simplest questions about the interaction of sympathetic amines and their receptors"13. It is sometimes possible, however, to construct working hypotheses about biochemical mechanisms involved which can be tested by experiment. In this case two such hypotheses have already been formulated9 and one of these is currently being tested directly. Furthermore, the technique described in programme 3b can often give further useful data for this purpose.
- (3) The data obtained by the processes described in the preceding paragraph may enable us to construct specific and testable working hypotheses as to the nature of the biochemical lesion in schizophrenia. The current hypotheses on this topic are based on a simple comparison of the molecular formulae of the hallucinogens and the central transmitting agents and therefore a knowledge of their mode of action may be expected to generate better working hypotheses. It seems likely that there are no short cuts here and much more basic work needs to be done before we can arrive at telling hypotheses in this field: the recent confusion over the "pink spot" indicates this clearly enough.

Criticism of the General Hypothesis

Finally, the general hypothesis outlined here has been criticized (largely under the influence of the dis-

appointment that the "pink spot" might be only a red herring) as having yielded only meagre results in its 15 years of existence.

A hypothesis, as long as it is not actually refuted, can only be judged on results; that is to say, on the previous disparate phenomena that it explains and the predictions it makes that can be tested by experiment. I have described the research programme suggested by this general hypothesis which is designed chiefly to generate even more specific predictions and hypotheses; for this we need to know much more about the mode of action of psychotomimetic drugs. The particular specific hypothesis formulated may well be false. It is certainly readily falsifiable. If it is, this possibility can be cleared out of the way and a new specific hypothesis constructed from our basic premises, but this can only be done if we have more facts. I should like to conclude by listing the known facts in this field which the general hypothesis can account for.

(1) The clinical correlation between schizophrenia and stress14 and the malignancy of the condition (through the vicious circle that would be set up if the stress mechanism were itself to elaborate highly stress-producing compounds). (2) The clinical links between schizophrenia and depressive illness and Parkinsonism (which may then be related to disorders in the metabolism of noradrenaline. 5-hydroxytryptamine and dopamine, respectively). The fact that the known hallucinogens are O- or N-methyl derivatives of the central transmitters (noradrenaline. 5-hydroxytryptamine and dopamine) or are derivatives of neurohumours (melatonin). Any theory that cannot account for this fact loses credence. (4) The therapeutic effect of the phenothiazines, which inhibit central adrenergic mechanisms18 as well as inhibiting N-methyl transferase. (5) The reported effect of methionine-monoamine oxidase inhibitor mixtures on schizophrenia16.

The hypothesis is merely a working hypothesis: however, as Kety¹⁷ has said, it is the best that we have at the moment. One should certainly keep an open mind about other hypotheses, but at present there is none in the field that can account for the phenomena.

The current sad muddle that constitutes so much of schizophrenia research might be alleviated if a coordinated interdisciplinary and interdepartmental programme were to be set up along the lines described here. In the United States brisk work along these lines is already under way and work is developing in the Soviet Union. In Britain, however, there is only a handful of people engaged in research into the biochemical basis of schizophrenia, which seems odd, because schizophrenics still occupy more than one quarter of the hospital beds in the country.

Site of Attachment of Retinal in Rhodopsin

by DERIC BOWNDS*

Biological Laboratories of Harvard University, Cambridge, Massachusetts

On illumination, rhodopsin passes through several unstable intermediates to a final mixture of retinal and opsin. One of these intermediates, metarhodopsin II, can be reduced by sodium borohydride to bind irreversibly the prosthetic group retinal to opsin in secondary amino linkage.

THE rhodopsins are the visual pigments most abundantly found in vertebrate retinas. They contain the 11-cis isomer of retinal (vitamin A aldehyde, formerly called retinene), bound as a prosthetic group to a lipoprotein moiety (opsin). The chief action of light is to convert this isomer to the all-trans configuration, a process followed in the dark by the formation of several transient intermediates and the eventual liberation of free trans retinal (see Fig. 1). In the course of this reaction sequence, usually referred to as the bleaching of rhodopsin, nervous excitation of visual cells is initiated.

The work of Collins² and Morton and Pitt³ suggests that a Schiff base linkage binds retinal to opsin

$$\mathrm{C_{19}H_{27}CH}{=}\mathrm{O} + \mathrm{H_2N\text{-}opsin} \rightarrow \mathrm{C_{19}H_{27}CH}{=}\mathrm{N\text{-}opsin} + \mathrm{H_2O}$$

A previous paper has shown that such a linkage is in fact exposed when cattle rhodopsin is bleached by light and can be reduced by sodium borohydride

$$C_{19}H_{27}CH$$
=N-opsin $\xrightarrow{NaBH_4}$ $C_{19}H_{27}CH_2NH$ -opsin $\xrightarrow{4}$

The carbon-nitrogen double bond apparently becomes accessible as the intermediate metarhodopsin II forms; it is probably exposed by conformational changes in opsin which are known to accompany the transformation of metarhodopsin I to metarhodopsin II (Fig. 1). The product of the reduction is an N-retinyl-opsin, a rhodopsin derivative in which a stable secondary amine linkage binds the fluorescent prosthetic group to the site which it occupies in metarhodopsin II. Furthermore, this site is probably the same one which the retinyl group occupies in native rhodopsin⁴.

The irreversible attachment of the retinyl group to opsin provides a handle which can be used to probe the active site of cattle rhodopsin and to identify the group to which retinal is bound. One would like, eventually, to explain why the binding of 11-cis retinal cattle rhodopsin causes a shift in its absorption maximum from 382 mμ to 498 mμ, from the ultraviolet to the blue green portion of the spectrum. Hubbard has suggested that this shift involves the binding of 11-cis retinal to opsin as a protonated Schiff base (C₁₉H₂₁CH=NH-opsin), with groups on opsin causing a displacement of the positive charge into the polyene system of the retinyl group, thus promoting resonance and so shifting the spectrum towards the red*.

To help evaluate this and other hypotheses which have been suggested, one needs to know what groups occur

* Present address: Department of Neurobiology, Harvard Medical School, Boston, Massachusetts.

near the retinal in rhodopsin. This article identifies the residue on opsin which binds retinal, and provides an analysis of the amino-acids which are covalently linked in its immediate neighbourhood. The picture which emerges will be completed only when one also knows which groups the tertiary structure of rhodopsin brings close to the prosthetic group, for these probably also contribute to the development of colour.

Identification of the Residue which binds Retinal in N-retinyl-opsin

N-retinyl-opsin can be prepared in quantity by irradiating rhodopsin solutions in the presence of sodium borohydride. These solutions are obtained by extracting membrane preparations of rod outer segments with 2 per cent aqueous digitonin. They contain rhodopsin on a large micelle with digitonin.

N-retinyl-opsin was prepared by irradiation for 5 min, at room temperature, of 70 ml. of a 5×10^{-5} molar solution of rhodopsin which had been brought to pH 8 with 1 normal sodium hydroxide, and made 10^{-2} molar in sodium boro-

$$\begin{array}{c} \text{Rhodopsin} \quad (498 \text{ m}\mu) \\ \downarrow \quad h^{\nu} \\ \text{Pre-lumirhodopsin} \quad (543 \text{ m}\mu) \\ \downarrow \\ \downarrow \\ \text{Lumirhodopsin} \quad (497 \text{ m}\mu) \\ \downarrow \\ \text{Metarhodopsin} \quad I \quad (478 \text{ m}\mu) \\ \downarrow \\ \uparrow \\ \text{Metarhodopsin} \quad II \quad (380 \text{ m}\mu) \\ \\ C_{19}H_{27}C = N \text{-opsin} \\ \downarrow \\ H_{10} \\ \end{pmatrix} \\ \text{All-trans retinal} \quad (387 \text{ m}\mu) + \text{opsin} \\ C_{19}H_{27}C = O + H_{2}N \text{-opsin} \\ \downarrow \\ H \\ N \text{-retinyl-opsin} \quad (333 \text{ m}\mu) \\ C_{19}H_{27}CH_{2}NH \text{-opsin} \end{array}$$

Fig. 1. Intermediates in the bleaching of cattle rhodopsin. Absorption maxima are shown in parentheses. Between —15° C and 5° C metarhodopsin I and metarhodopsin II exist in an equilibrium in which formation of metarhodopsin II is favoured by increases in temperature, acldity, and glycerol or neutral salt concentration. The normal bleaching sequence can be interrupted at the stage of metarhodopsin II by sodium borohydride, which reduces the Schiff base linkage between retinal and opsin before its hydrolysis can occur.

hydride. A Sylvania 'Sun Gun' which had been filtered to pass only wavelengths between 400 and 700 m μ was used as the light source. The N-retinyl-opsin solution was dialysed against water overnight at 4° C to remove excess borate ions, and was stored at 4° C. The fluorescence of the retinyl group, which has its excitation maximum at 330 m μ and emission maximum at about 480 m μ , could be observed in solutions and on chromatograms with an ultraviolet hand lamp. The molar extinction of the retinyl group is approximately 50,000 at 333 m μ (ref. 8).

N-retinyl-opsin was broken down to its constituent amino-acids by alkaline rather than acid hydrolysis because the retinyl group is destroyed by acids. N-retinylopsin solutions (usually 10-20 ml. 5×10^{-5} molar in the retinyl group) were made 2 normal in sodium hydroxide, evacuated and flushed three times with nitrogen in a 'Teflon' test tube, sealed under nitrogen and kept at 100° C The hydrolysate was applied to a column of for 6 h. silica gel HR (Merck-Brinkman) 15 cm long and 2.5 cm in diameter which had been prepared in chloroformmethanol-ammonium hydroxide in the volume ratio 70-27-3, and was eluted with the same solvent. fluorescent fractions were obtained, of which the second had the absorption spectrum of the retinyl group and accounted for half of the retinyl group present in N-retinylopsin before alkaline hydrolysis.

Fig. 2 shows the chromatographic mobility of this retinyl compound compared with six N-retinyl aminoacids. Each of the N-retinyl amino-acids, the synthesis of which is described in Fig. 3, was prepared in a volume

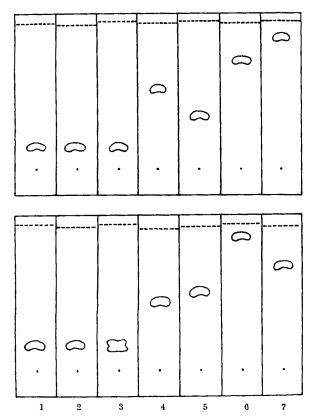

Fig. 2. Thin layer chromatography of the N-retinyl compound from N-retinyl-opsin and known N-retinyl amino-acids. A 250µ layer of silica gel MR (Merck) was applied to a 20×20 cm glass plate, scored into 3 cm zones, and 10-20 µl. portions of the retinyl compounds were applied 2·5 cm from the bottom of the plate. In the top chromatogram n-butanol-acetic acid-water in the volume ratio 80: 18: 2 was used as the eluting solvent. Chloroform-methanol-ammonium hydroxide (70: 27: 3) was used in the bottom chromatogram. Zone 1, N-retinyl-lysine; zone 2, the retinyl compound from N-retinyl-opsin; zone 3, N-retinyl-ornithine; zone 4, N-retinyl-aspartate; zone 5, N-retinyl-histidine; zone 6, N-retinyl-valine; zone 7, N-retinyl-tryptophan.

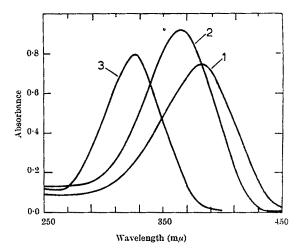

Fig. 3. Synthesis of an N-retinyl amino-acid. Curve 1 is the spectrum of all-trans retinal in 60 per cent aqueous methanol (1·7 × 10·5 molar; λ_{\max} 383 m μ). A 200-fold molar excess of alanine was added and the pH was adjusted to 9·5 by adding 1 normal sodium hydroxide. After 20 min the retinal had been converted to the Schiff base N-retinylidene—

alanine (curve 2; λ_{\max} 367 m μ ; $C_{10}H_{c2}C=N-CHC00^-$). Addition of 10 mg of powdered sodium borohydride reduced this Schiff base to the corresponding secondary amine. N-reliayl-alanine (curve 3; λ_{\max})

CH₃ 328 mμ; C₁₉H₂₇CH₂NHCHCOO).

of 20 ml. Fifteen ml. were then evaporated almost to dryness and passed through the same hydrolysis and column procedure as N-retinyl-opsin. All survived in 40-60 per cent yield, with their spectra and chromatographic mobilities remaining unchanged. The mobility of the retinyl compound obtained from N-retinyl-opsin was compared also with fifteen other N-retinyl amino-acids prepared from common amino-acids.

The retinyl compound from N-retinyl-opsin could not be distinguished from N-retinyl-lysine or N-retinyl-ornithine (the next lower homologue of N-retinyl-lysine) in thin layer chromatography9 (compare also Akhtar et al.¹⁰). Because N-retinyl-ornithine is a product of the alkaline decomposition of N-retinyl-arginine, the retinyl compound from N-retinyl-opsin could have been derived from either an N-retinyl-arginine or an N-retinyl-lysine residue which was present in N-retinyl-opsin before alkaline hydrolysis. To bind the retinyl group, however, arginine would have to be an N-terminal amino-acid of opsin, for only the a-amino group of arginine reacts with retinal to form a Schiff base. Attempts to find an N-terminal residue in either rhodopsin or opsin have so far been unsuccessful¹¹. The use of alkaline hydrolysis introduced a further ambiguity: in 2 normal sodium hydroxide at 110° (' the retinyl group undergoes an intramolecular rearrangement between the a- and s-amino groups of lysine, but does not pass to the amino groups of any other amino-acids which may be present. This rearrangement could be demonstrated by hydrolysing α -N-acetyl- ϵ -retinyl-lysine in 2 normal sodium hydroxide. The product was a mixture of α -N-retinyl-lysine and ϵ -N-retinyl-lysine. Reacetylation produced both α-N-acetyl-ε-N-retinyl-lysine and α-Nretinyl-ε-N-acetyl-lysine which (unlike α-N- and ε-Nretinyl-lysine) could be readily distinguished in thin layer chromatography8.

For this reason, alkaline hydrolysis was of limited usefulness in breaking down N-retinyl-opsin to a single N-retinyl amino-acid. Nor could acid hydrolysis be used, because it destroys the retinyl group and the ninhydrin colour of N-retinyl-lysine. Also, no combination of enzymes hay yet been found that releases a single N-retinyl amino-acid from N-retinyl-opsin⁸. Enzyme hydrolysis could, however, be used to free small peptides containing the retinyl group from N-retinyl-opsin^{8,12}. These peptides.

like N-retinyl-opsin, yielded a compound with the chromatographic mobility of N-retinyl-lysine on alkaline hydrolysis. The smallest peptide of this nature also had a free N-terminal residue which was not lysine, indicating that the retinyl group must be attached to an internal amino group. This is presumably the s-amino group of a lysyl side chain.

N-retinyl-opsin Peptides containing the Retinyl Group

Pronase, a mixture of proteases from Streptomyces griseus, was used to liberate small N-retinyl peptides from N-retinyl-opsin. A number of other enzymes, trypsin, chymotrypsin, pepsin and papain, effected some proteolysis in solutions of N-retinyl-opsin but left the retinyl group bound to a large undigested protein moiety. Proteolysis was most rapid when pronase was added directly to solutions of micellar N-retinyl-opsin (that is, still containing sufficient phospholipid and digitonin to render soluble the N-retinyl-protein present). When the digitonin and phospholipid were removed by ethanol extraction, the N-retinyl-protein precipitated and its complete digestion in aqueous suspension required several days.

In the digestion shown in Fig. 4, 10 ml. of a solution of N-retinyl-opsin (5 × 105 molar in retinyl group), containing a small crystal of thymol, was incubated with pronase under nitrogen at pH 7-3 and 30° C. Fresh pronase (Calbiochem, grade B) equal to about 2 per cent of the weight of the N-retinyl-opsin was added every 4 h and the pH was maintained at 7.3 by occasional additions of 0-1 normal sodium hydroxide. The fluorescent N-retinylpeptides freed by pronase digestion were soluble in ethanol and accounted for 60-70 per cent of the retinyl group present before digestion (Fig. 4). Their liberation was virtually complete after 14 h of digestion, and their relative concentrations and mobilities in thin layer chromatography did not change on further digestion. The retinyl material which did not become ethanol-soluble during the course of digestion remained bound to an N-retinyl-protein residue soluble in 75 per cent formic acid.

Columns of silica gel HR (Merck) were used to resolve these peptides. For the chromatogram shown in Fig. 5 an ethanol extract of a 14 h old pronase digest of N-retinylopsin (containing approximately 3×10^{-6} moles of retinyl group) was evaporated almost to dryness, dissolved in 5 ml. of chloroform-methanol-ammonium hydroxide in

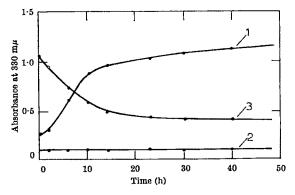

Fig. 4. Digestion of N-retinyl-opsin by pronase. Ten ml. of a solution of N-retinyl-opsin was incubated under nitrogen with pronase at pH 7·3 and 30° C. Samples (1 ml.) were removed at various times, lyophilized, and extracted with two 1 ml. portions of 99 per cent ethanol. The absorption of the pooled ethanol extracts at 330 mx is shown in curve 1. This provides a measure of the retinyl compounds extracted. The material in each aliquot left after ethanol extraction was then extracted with 2 ml. of water and the absorption of these extracts at 330 mx is shown in curve 2. Apparently no retinyl derivatives are water-soluble. Curve 3 is the absorption at 330 mx of the remaining residues dissolved in 75 per cent formic acid. This indicates the amount of rethyl material still bound to an indigestible protein fraction soluble only in 75 per cent formic acid; it accounts for one third of the retinyl group originally present in N-retinyl-opsin.

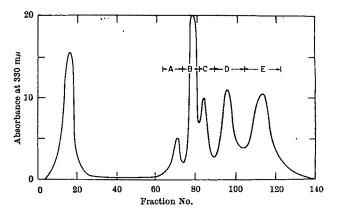

Fig. 5. Column chromatography of N-retinyl-peptides. The absorption of the first peak at 330 m μ does not reflect the presence of the retinyl group but is associated with the tail end of a large absorption band at 280 m μ ; this material moves with the solvent front and contains decomposed lipids and retinyl compounds.

the volume ratio 70: 27: 3, and put on a column of silica gel HR, 30 cm in length and 2.5 cm in diameter, which had been prepared in the same solvent. Only glass and 'Teflon' parts were used in constructing the column. A solvent reservoir containing the same solvent was connected, the system was put under nitrogen pressure of 5 lb./in.², and 2 ml. fractions were collected. The elution of discrete fluorescent retinyl-containing bands could be observed using an ultraviolet hand lamp. Of the retinyl compounds applied to these columns, 50-60 per cent were recovered in the fractions collected. The remainder was very strongly adsorbed to the columns, and could not be removed with the solvents used.

The spectra of the cluted peptides were virtually identical with the spectrum of N-retinyl-alanine shown in Fig. 3, curve 3. Peaks B, C, D and E, containing approximately half the N-retinyl material which cluted from the column of Fig. 5, were further purified by chromatography on columns of silica gel HR, 60 cm long and 0.9 cm in diameter, using the procedure just indicated. Peak A did not contain enough material to make further chromatography worth while, and N-retinyl-peptides cluted from the column after peak E (not shown in Fig. 5) have not yet been purified.

Table 1. Amino-acid analyses of n-retinyl material eluted from the column shown in fig. 5, after further purification, and hydrolysis in 6 normal hydrochloric acid

Residues present (N-		Pooled	fractions	
retinyl-lysine group)	В	C	D	E
Threonine Proline Alanine Isoleucine Phenylalanine	1·2 (1) 2·3 (2)	1·1 (1) 1·4 (1) 2·6 (3) 1·4 (1) 2·7 (3)	1·0 (1) 1·0 (1) 2·2 (2) 1·1 (1) 1·8 (2)	1·2 (1) 0·9 (1) 1·9 (2) 1·1 (1) 2·8 (3)

N-retinyl-lysine does not appear in these analyses because it is destroyed by acid.

Each of the purified N-retinyl peptide fractions was hydrolysed in 6 normal hydrochloric acid for 24 h. Longer hydrolysis did not produce further changes. These purified fractions each contained 1 to 5×10^{-8} moles of retinyl compounds. Amino-acid analyses of the rechromatographed peaks B, C, D and E are shown in Table 1, expressed as moles of amino-acid/mole of N-retinyl-lysine. N-retinyl-lysine does not appear in these analyses because both its ninhydrin colour and the retinyl group are destroyed by acid. All these peptide fractions, however, yielded a compound with the chromatographic mobility of N-retinyl-lysine on alkaline hydrolysis.

The N-retinyl amino-acid present in these peptides was ε-N-retinyl-lysine. This follows from the fact that the smallest peptide had phenylalanine as its N-terminal residue; this was identified with the N-terminal reagent 1-dimethyl-amino-naphthalene-5-sulphonylchloride⁸. With the N-terminal residue of this peptide free, the retinyl group must have been bound to an internal amino group, the ε-amino group of lysine. This smallest peptide was obtained pure in fraction B, and the compositions of the larger peptide fractions, C, D and E, were probably those indicated in parentheses in Table 1. The possibility that some of these fractions were heterogeneous, however, cannot be excluded. The largest peptide fraction had the average composition of the decapeptide: phe3, ala3, ileu, pro, thr, ε-N-retinyl-lys.

The amino-acid residues of N-retinyl-opsin listed in Table I occur adjacent to the lysine residue, the s-amino group of which binds the retinyl group. Presumably this same amino group binds retinal in metarhodopsin II and in native rhodopsin. The peptides containing these residues have overlapping compositions, as one would expect if borohydride reduction anchored the retinyl group to a single site in N-retinyl-opsin, and pronase cleaved a number of nearby peptide bonds. The smallest peptide has the composition phe2, ala, E-N-retinyl-lys, to which the larger peptides add thr, pro and ileu, plus additional alanine and phenylalanine.

The preponderance of non-polar side chains in these peptides indicates that they compose a hydrophobic region of the N-retinyl-opsin lipoprotein, perhaps not in direct contact with the aqueous medium. This might be the reason why they are difficult to free by enzyme hydrolysis, thus only the pronase mixture of non-specific proteases from Streptomyces griseus will hydrolyse these peptides. This hydrophobic environment might also tend to keep the ε-NH₂ group of lysine non-protonated at neutral pH, thus promoting its combination in Schiff base linkage with the aldehyde group of 11-cis retinal to form rhodopsin¹³. (In free solution the ε-amino group of lysine is

protonated at neutral pH, and can combine with retinal only at pH greater than 9 (ref. 14).)

It seems reasonable to assume that the retinyl group itself exists in a hydrophobic environment both in N-retinyl-opsin and in native rhodopsin. It is difficult to say what influence this environment might have on the colour of cattle rhodopsin. The significance of the residues in the peptide to which the retinyl group is covalently bound could be better assessed if one had for comparison similar data on other visual pigments. In this regard it would be most interesting to examine the peptide which binds retinal in chicken iodopsin which, although it has the same prosthetic group as cattle rhodopsin, absorbs much further in the red region of a spectrum (λ_{max} 562 m μ).

I thank Professor George Wald, Dr Ruth Hubbard. Paul K. Brown and Dr Guido Guidotti for their advice and encouragement, and Steve Roper, Harry Fegley and Miss Julia Currie for technical assistance. This work was supported by predoctoral fellowships from the US National Institutes of Health and the National Science Foundation, and by a National Science Foundation research grant to Professor Wald.

Amino-acid Sequence of Glyceraldehyde 3-Phosphate Dehydrogenase from Lobster Muscle

bу

B. E. DAVIDSON* M. SAJGÒ† H. F. NOLLER‡ J. IEUAN HARRIS

MRC Laboratory of Molecular Biology, Hills Road, Cambridge

The protein sub-unit of glyceraldehyde 3-phosphate dehydrogenase consists of a single chain of 333 amino-acid residues, corresponding to a molecular weight of 36,000. Amino-acid sequence studies show that the active enzyme-NAD complex with a molecular weight of 146,000 is composed of four protein chains of identical sequence.

GLYCERALDEHYDE 3-phosphate dehydrogenase (GPDH) plays an important part in carbohydrate metabolism.

In the presence of NAD and phosphate it catalyses the reversible oxidative phosphorylation of glyceraldehyde 3-phosphate to 1,3-diphosphoglycerie acid and as such it participates in the glycolytic conversion of glucose to pyruvic acid in most living organisms. Since its original isolation from yeast by Warburg and Christian¹ the crystalline enzyme has been prepared²⁻⁵ from a wide range of species and has been the subject of much chemical and kinetic investigation6,7.

No. of residues/36,000 g of protein

A chemical study of the enzyme from pig muscle led Harris and Perham⁸ to conclude that GPDH from any given species is composed of four similar, and probably identical, protein chains, each containing approximately 330 amino-acid residues (corresponding to a molecular weight of 36,000), including one catalytically active cysteine^{9,10}. Among NAD-linked dehydrogenases, muscle GPDH is unique in having high affinity for NAD, and the active tetramer has the capacity to bind up to four moles of the coenzyme¹¹. It has been shown that the binding sites are not equivalent and that a marked conformational change^{12,13} involving some form of co-operative interaction between the protein chains¹⁴ occurs when the first molecule of NAD is bound to the apo-enzyme. The enzyme-NAD complex would thus have a molecular weight of between 144,000 and 147,000 according to its content of bound NAD, and values recently obtained 15 by sedimentationequilibrium methods are in agreement with those predicted from the chemical data8.

Studies of haemoglobin¹⁶ and of monomeric enzymes such as lysozyme¹⁷, chymotrypsin¹⁸ and ribonuclease¹⁹ have shown how a knowledge of the three-dimensional structure of an enzyme can be used, in conjunction with chemical and kinetic information, to investigate mechanisms of enzyme catalysis. Similarly, in our view, a detailed knowledge of the three-dimensional structure of the protein chains in GPDH, and of the specific arrangement by which these chains associate and interact to form the quaternary structure of the active tetramer, will be necessary before the mechanism of enzyme catalysis can be fully understood. This detailed structure can be obtained by interpretation of X-ray diffraction analysis of crystals in conjunction with a knowledge of the aminoacid sequence of the enzyme protein. Of all the GPDHs which have been crystallized, the enzyme from lobster muscle⁵ has proved to be the most suitable for analysis by X-ray diffraction methods. The crystal structure of lobster GPDH is being studied by Dr H. C. Watson and his colleagues in this laboratory²⁰. We have therefore determined the amino-acid sequence of the protein sub-unit in the enzyme and a preliminary account of this work is given in this communication. A separate study⁸ of the amino-acid sequence of GPDH from pig muscle (J. I. Harris and R. N. Perham, unpublished results) will be published elsewhere.

Determination of Amino-acid Sequence

GPDH was prepared from lobster tail muscle as previously described. The amino-acid composition, based on a molecular weight of 36,000 (ref. 8) and given in Table 1, indicates that the protein sub-unit consists of about 330 residues. This composition is in good agreement with the earlier data of Allison and Kaplan⁵, except that it indicates the presence of an additional residue of cysteine and of arginine.

Studies of the amino-acid sequence were carried out chiefly with the N-trifluoroacetyl-S[14C]-carboxymethylenzyme. This derivative was prepared by carboxymethylation of the five cysteine residues with [2-14C] iodoacetic acid in 8 molar urea at pH 8.2 (ref. 8), followed by trifluoroacetylation²¹ of the twenty-eight lysine residues in the continued presence of a large excess of S-ethyltrifluorothioacetate in 8 molar urea at pH 10.0 (unpublished results of Harris and Perham). Digestion with trypsin (1 per cent) was carried out in a pH-stat for 10 h at pH 8.5 and 25° C. The average number of peptide bonds which were hydrolysed by trypsin in these conditions was approximately equivalent to the total number of arginine residues (nine) per mole of protein.

The resulting mixture of peptide fragments gave rise to five separate components by gel-filtration on 'Sephadex G-50' in 0.1 molar ammonium bicarbonate (pH 8.0). The smaller components yielded pure peptide fractions by ionophoresis on paper, and the larger components were

purified by ion-exchange chromatography on DEAEcellulose in 8 molar urea containing tris-hydrochloric acid buffer at pH 7.5. In this manner, ten unique peptides (nine with C-terminal arginine, and one, the C-terminal peptide in the protein chain, with C-terminal alanine) were identified among the products of trypsin digestion. These peptides contained 3, 3, 4, 10, 14, 14, 32, 34, 43, and from 175–180 amino-acid residues, respectively, giving a total of about 335 residues.

 - * Estimated as cysteic acid and methionine sulphone, respectively, † Estimated by extrapolation to zero time of hydrolysis. ‡ Estimated by extrapolation to infinite time of hydrolysis. § Not determined.

Purified peptides which contained N-trifluoroacetyllysine were separately redigested with trypsin after removing the blocking group with M piperidine at 0° C (ref. 21). The resulting mixtures, which now contained lysine peptides in addition to the peptides containing C-terminal arginine, were purified by suitable combinations of gelfiltration, paper ionophoresis at various pHs and paper chromatography. The amino-acid sequences of the purified peptides were determined by standard methods with major reliance on stepwise analysis by the dansyl-Edman procedure²². Overlaps of lysine residues were obtained from the sequences of peptides produced with chymotrypsin, pepsin, papain or cyanogen bromide; the lysine diagonal method²³ was occasionally used to facilitate the purification of these peptides. Tryptic peptides which contain arginine occupy C-terminal positions in the original lysine-blocked fragments, and the relative order of these fragments along the protein chain was established from the sequences of peptides containing arginine, which were obtained from pepsin or chymotrypsin digests of the S-[14C] carboxymethyl-protein. The N-terminal trypsin peptide in the protein chain was found to be N-acetyl.Ser.Lys. The acetyl group was identified as acetylhydrazide after hydrazinolysis of the N-substituted peptide, and by mass spectrometry. Peptides which contained tryptophan were detected on paper by Ehrlich's reagent and the number of tryptophan residues in each of the purified peptides was established by the dansyl-Edman method (residues 192 and 309 (Fig. 1)) or by spectrophotometric analysis (residue 83). By these methods three residues of tryptophan were found in peptide fragments in contrast to the value of four obtained by spectrophotometric analysis of the intact enzyme protein. The reason for this discrepancy has not been established, but it is possible that the value obtained by direct analysis of the protein is high because of the presence of bound NAD. Amide

groups have been provisionally assigned from the electrophoretic mobilities²⁴ of peptides which contained aspartic and glutamic acids.

These results enable us to propose the following provisional amino-acid sequence for the protein sub-unit of lobster GPDH (Fig. 1). It consists of a single chain of 333 amino-acid residues (including N-terminal N,acetylserine), corresponding to a molecular weight of 36,003. The active tetramer would thus have a molecular weight of 144,012, or 146,650 if it contains four moles of bound NAD (compare pig GPDH, refs. 8 and 15).

Details of the experimental results on which the sequence is based cannot be given in this short communication. We therefore present the following evidence in support of its

(1) The amino-acid composition derived from the proposed sequence is in excellent agreement with the composition calculated from the experimentally determined amino-acid analysis of the enzyme protein (Table 1). (2) All the tryptic peptides which occurred in major yield were purified and are unambiguously accommodated in the sequence. The sequence of 333 residues thus represents a complete recovery of the analysed parts. (3) All the lysine and arginine residues have been unequivocally overlapped, many with peptides derived from more than one type of digest. (4) Stepwise analysis by the Edman method, coupled with the identification of successively released amino-acid residues as their dansyl derivatives, was carried out through all the peptide bonds in the sequence (in many instances on more than one type of

fragment, and on separate occasions), with the exception of the bonds between residues 1-2, 2-3, 83-84, 98-99, 135-136, 158-159, 175-176, 190-191 and 255-256. Sequences obtained by the dansyl-Edman method were in agreement in all cases with the amino-acid compositions of the analysed peptides and in most cases the sequences obtained in this way were confirmed by analysis of other fragments obtained by digestion with suitable proteolytic enzymes. (5) Finally, the validity of the sequence of the lobster enzyme receives additional support from a comparison with the sequence of the pig muscle enzyme (unpublished results of Harris and Perham). In many instances sequence homologies between the two proteins provide a valuable check on the accuracy of the two independently determined sequences. Further confirmatory evidence will continue to be sought in the course of work which is being undertaken to establish the identity of other reactive groups in the enzyme.

Discussion of Methods

The use of methods based on the reversible blocking of lysine residues has greatly facilitated the sequence analysis of lobster GPDH. With proteins of smaller size (for example, ribonuclease)²⁵ the conventional first step has been to isolate and to work out the sequence of all the peptides from a total trypsin digest of the complete protein. The order in which the various trypsin peptides occur in the protein chain is then established from the sequences of a selection of different peptide fragments containing lysine and arginine; these are obtained by

Fig. 1. Amino-acid sequence of glyceraldehyde 3-phosphate dehydrogenase from lobster muscle. The sequences of the tryptic peptide containing Cys-148 (residues 139 to 158); the N-terminal dipeptide (X.Ser).Lys, and the C-terminal tetrapeptide Val(Asp,Ser).Ala were determined previously (Allison and Harris**; W. S. Allison, unpublished results).

alternative methods of fragmentation such as pepsin, chymotrypsin or cyanogen bromide. Trypsin digests of larger proteins contain on average a correspondingly larger number of peptides. A digest of lobster GPDH, for example, contains a total of more than forty peptide fragments (including products of partial digestion of slowly hydrolysed bonds, and of cleavages at bonds other than those involving the twenty-eight lysine and nine arginine residues), and it has proved difficult to obtain all the necessary peptides in pure form from complex mixtures such as these^{8,28}.

In order to reduce the number of peptides to be fractionated from such a mixture, we attempted to limit the action of trypsin to the nine arginyl bonds in lobster GPDH by reacting the \(\epsilon\)-amino groups of the lysine residues with S-ethyltrifluorothioacetate^{21,23} (or with maleic anhydride²⁶, unpublished results). This procedure proved to be highly advantageous in that trypsin digests of the resulting lysine-blocked proteins, like their counterparts from the pig enzyme (unpublished results of Harris and Perham), were completely soluble, and readily amenable to fractionation by standard methods. The ten major peptide components which were obtained in this way (see earlier section) could then be studied separately.

Peptides which contained blocked lysines were unblocked to regenerate lysine residues, and the unblocked peptides were then separately redigested with trypsin. digests were relatively easy to fractionate because in each case they contained only those tryptic peptides that occur between two consecutive arginine residues in the protein chain. The isolation of the tryptic peptides from lobster GPDH was thus accomplished more simply by a series of separate fractionation steps from lysine-blocked fragments than by direct fractionation of the complex mixture of more than forty peptides which is produced by digestion of the unblocked protein with trypsin. Similarly, peptides which overlap lysine residues are also obtained more easily (for example, by the lysine diagonal method 23,28) from suitable digests of lysine-blocked fragments than from the considerably more complex mixtures of peptides that occur in similar digests of the whole protein. In this way the sequences of N-trifluoroacetyl- (and of maleyl26) peptides can be determined in a series of separate operations. The complete sequence of the protein chain is then established by overlapping arginine residues with peptides obtained from suitable digests of the whole protein as described earlier.

The overall strategy which has been developed for determining the amino-acid sequence of lobster GPDH is clearly applicable to other proteins of similar, or even larger, size. Many other important enzymes such as yeast and liver alcohol dehydrogenases, lactic dehydrogenase and aldolase, to mention but a few, are known to consist of sub-units comparable in size to those of GPDHs, and we suggest that the method of reversible lysineblocking could be used to similar advantage in the sequence analysis of these enzymes. Ideally, it is desirable that the protein to be studied should contain a sufficient number of lysine and arginine residues, and the method will work best if there are from two to three times as many lysines as there are arginines; moreover, it is also advantageous if arginine residues are fairly evenly distributed along the protein chain. This is exemplified by the case of lobster GPDH where the uneven distribution of arginine residues gave rise to one large lysine-blocked fragment (residues 18 to 193, Fig. 1) containing 176 amino-acid residues, including sixteen lysines. This fragment was obtained in low yield partly because of its susceptibility to chymotrypsin-like cleavages during trypsin digestion, and also because of severe losses during chromatography on DEAE-cellulose. Consequently, in order to determine the sequences of some of its constituent lysine-containing peptides, it proved in some circumstances to be more convenient to obtain additional amounts of these peptides from a tryptic digest of the unblocked protein.

Relationships between Structure and Activity

The amino-acid sequence of lobster GPDH presented here provides strong evidence for the chemical identity of the four protein chains comprising the active enzyme molecule. At first sight the active enzyme could therefore be envisaged as consisting of four structurally equivalent monomer chains, each chain (α) containing a reactive cysteine which in conjunction with NAD and phosphate would be capable of promoting the catalytic reaction within the quaternary structure of the tetramer.

X-ray diffraction studies²⁰ of crystals of the enzyme-NAD complex suggest, on the other hand, that the tetrameric molecule could consist of structurally identical pairs of sub-units. This concept is supported by recent spectrophotometric evidence which indicates that the molecule exhibits chemical as well as structural asymmetry (S. A. Bernhard, personal communication). In this respect, the GPDH-NAD complex is similar in structure to haemoglobin¹⁶ in which two chemically different sub-units are related in pairs to form the tetrameric molecule.

One way of reconciling these results with the identity of chemical sequence would be to postulate that crystals of the apoenzyme possess a symmetrical tetrameric (α_4) structure which changes to the $\alpha_2\alpha_2$ ' type of structure as the result of conformational changes which occur when NAD binds to the protein sub-units. Conformational changes involving co-operative interactions between the monomer chains are known to occur when NAD interacts with the apoenzyme in solution^{12–14}. Attempts to compare the crystal structure of the NAD-enzyme with that of the apoenzyme have not so far been possible because the apoenzyme, unlike that of lactic dehydrogenase²⁷, does not seem to crystallize in the absence of the coenzyme.

In a previous study of lobster GPDH, Allison and Harris²⁸ showed that Cys-148 reacts selectively with iodoacetic acid in the native enzyme. Moreover, the amino-acid sequence around this reactive cysteine (residues 143–155, including a second but unreactive cysteine in position 152) was shown to be identical with the sequences around the corresponding reactive cysteine in GPDHs from several other species^{8,10,28}. It has now emerged that the other three cysteines in lobster GPDH (positions 22, 129, 249) are not homologous with cysteine residues in other GPDHs. For example, in pig GPDH the corresponding positions are occupied by serine, methionine and valine, respectively (ref. 8 and unpublished results of Harris and Perham); the positions of the other two cysteines in the pig enzyme, on the other hand, are occupied by Val-243 and Ser-280 in the lobster enzyme. These variable cysteines are therefore unlikely to be specifically involved either in the catalytic activity or in maintaining the tertiary structure of active muscle GPDH.

Cys-148 participates in the catalytic reaction by attaching the substrate in thioester linkage to the enzyme (for example, refs. 9 and 10). In the absence of substrate (but in the presence, or absence, of NAD) it can also form an intrachain disulphide bond with Cys-152 (ref. 8). This shows that the two sulphydryl groups can occur in close proximity in the three-dimensional structure, and that the apparently unreactive sulphydryl group of Cys-152 could also prove to be an essential feature of the active molecule.

Another glimpse of the three-dimensional structure of the apoenzyme is provided by the observation that the acetyl group which is bound initially to Cys-148 (in the pig and rabbit muscle enzymes) during the enzyme-catalysed hydrolysis of p-nitrophenylacetate^{9,10} and acetylphosphate²⁹, respectively, is able to transfer to a specific lysine residue^{29,20} (shown to be Lys-182 in the pig enzyme)³¹ at a higher pH. The same reaction has now been shown to occur with lobster GPDH (unpublished re-

sults of B. E. Davidson) and a comparison of the sequences around the two reactive amino-acids in the pig32 and lobster enzymes reveals that forty-two of the forty-eight residues in this segment of the chain (positions 143-190) are identical in the two species. Moreover, the changes that have occurred are all of a conservative nature and could all have arisen as the result of a single base change in the Escherichia coli code33.

The remarkable conservation of the amino-acid sequence around the reactive cysteine and lysine residues in enzymes from such distantly related species as pig and lobster suggests that the three-dimensional conformation of this part of the protein chain has also been conserved, possibly because it contributes significantly to the structure of the "catalytic centre" of the enzyme. In this context the transfer of an acetyl group from the sulphydryl group of a cysteine in position 148 to the ϵ -amino group of a lysine in position 182 shows that these two groups can approach each other very closely within the three-dimensional structure of the tetrameric apoenzyme. Little is as yet known about the detailed arrangement of the protein chains within the tetramer and it therefore remains to be established whether the acetyl transfer reaction occurs within or between monomers and, more specifically, to what extent (if any) the interaction of amino-acid side chains from more than one monomer may be involved in the catalytic reaction itself.

The amino-acid sequence of the protein monomer in lobster GPDH provides a framework for the precise interpretation of the results of further chemical, kinetic and X-ray crystallographic studies on the active tetrameric molecule in solution, and in the crystalline state. GPDHs from all sources are likely to possess a similar three-dimensional structure and hence a common reaction mechanism. It is to be hoped that the combined results of chemical and X-ray diffraction studies now in progress will lead to the identification of the amino-acid side chains that bind the substrate, NAD and phosphate to the protein sub-unit, as a step towards elucidating the mechanism of enzyme catalysis.

We thank Dr W. S. Allison for the approximate aminoacid compositions of a number of tryptic peptides from

lobster GPDH, which he isolated in this laboratory during 1964. We also thank Mrs Beryl Preston for technical assistance.

Specific Binding of Sodium and Potassium Ions in Erythrocyte Membranes

by

B. Z. GINZBURG

T. FRIEDLANDER

E. POUCHOVSKY

Department of Botany, The Hebrew University, Jerusalem, Israel

In erythrocytes, the binding of sodium and potassium ions to sites in the membrane is specific and the number of sites is extremely small. Addition of ATP to the medium increases the binding of sodium ions by 50 per cent or more and it is suggested that ion binding is connected with the ion pump.

THE sodium-potassium ion pump which has been described in erythrocytes and in many other types of cell is one of the best known examples of a device for transduction of chemical energy into osmotic energy. It has been shown that ATP is the immediate source of energy for the ion pump in erythrocytes. It is also known that the ATPase system ("transport ATPase"), concerned with active ion transport, requires the simultaneous presence of Na+ and K+. The existence of two separate reaction sites is thus indicated^{1,2}. Whittam³ and Ĝlynn⁴ have provided proof that these two separate sites are

on opposite sides of the erythrocyte membrane. This spatial separation makes the system anisotropic, an a priori requirement for the coupling of a chemical reaction to diffusional flows across a membrane.

Recently^{5,6}, a model of the Na⁺-K⁺ pump in the erythro-

cyte membrane was proposed and analysed thermodynamically. This model is based on many others3,7,8. and is graphically represented in Fig. 1.

The principal features of this model are the existence of the specific binding sites for Na+ and K+ and their cyclic interconversion by chemical reactions, one of which in-

volves ATP as a reactant. In such a model, an increase in specific binding of Na+ should be at the expense of the specific binding of K+. Specific binding of Na+ and K+ has not been observed in erythrocyte membranes or other biological membranes, but its existence has been inferred from kinetic studies^{1,2}. Cohen⁹ has demonstrated the existence of specific binding sites for rubidium in the Chlorella membrane, and has studied their properties extensively. One remarkable feature was that the specific binding ability was retained in cells which had been treated with boiling ethanol. This clarifies somewhat the nature of the binding sites and has also very important practical application in our experiments. studies10,11 and also our own results, as will be shown later, indicate that the amount of "carrier" or number of binding sites is extremely small, of the order of 10-9 moles/ml. cells. It is very difficult to measure specific binding in such small amounts. By using hot ethanol on membrane fragments we have been able to concentrate the number of binding sites, thus enabling measurement of the specific binding of Na+ and K+.

The membrane preparation we have used resembles that used for measuring Na+-K+-activated ATPase by Dunham and Glynn¹² and Post et al. 13. After haemolysis, the erythrocyte membrane fraction was thoroughly washed in the cold with large volumes of 30 mmolar tris-hydrochloric acid buffer at pH 8.1, until no haemoglobin appeared in the supernatant. The membrane fraction was finally washed with 30 mmolar tris-hydrochloric acid at pH 7.2 containing 20 mmolar magnesium chloride. The resulting preparation was kept in a deepfreeze, and was tested for ATPase which had been activated with Na+ and K+ before the binding experiments were undertaken. A few experiments were also carried out on a rat brain membrane preparation using Skou's method¹⁴, modified somewhat by Edelman (personal communication). Such membrane preparations were treated either with 80 per cent boiling ethanol, with 5 per cent cold TCA, or by freezing in liquid air. The pellet resulting from any one of these treatments was resuspended in cold 20 mmolar magnesium chloride and 30 mmolar tris-hydrochloric acid at pH 7.2. Three different methods were used to measure the binding of Na+ and/or K+.

In the first method, 2 ml. of the suspension was filtered through a 'Millipore' filter (THWP). This filter, which was 25μ thick, was chosen because it contained only 7 mg of water when wet. The filtrand was rinsed several times with magnesium chloride and *tris* solution and was then equilibrated for at least 10 min with the same solution, to which radioactive Na⁺ had been added. Tests were made to show that longer periods of equilibration did not bring about more binding. The amount of bound ions was calculated as the difference between total counts and the

"solution correction". This last quantity represents the radioactivity of the solution which was trapped in the filter and the filtrand. The "solution correction" is the most important parameter in this experiment. It was checked that no radioactivity had been bound by the 'Millipore' filter and that, when the membrane preparation was treated with a concentrated solution of very low specific activity, all the measured radioactivity could be accounted for by trapped solution. The chief error is caused by some drying which occurs while draining the filtrand by the vacuum pump. It was found that this error could be minimized by standardizing the procedure.

In the second procedure, a known volume of membrane suspension was centrifuged in a weighed test tube. The supernatant was sucked off, and the test tube and pellet were weighed. Buffer solution containing a known amount of radioactive sodium was added and incubated with the membrane particles for 30 min. The supernatant was removed by centrifugation, its radioactivity was measured and its value was corrected for the water content of the original pellet. The difference between the original and corrected final radioactivities represented the ions bound by the membrane fragments.

According to the third method, the suspension of membrane fractions was centrifuged and washed three times in cold magnesium chloride and tris buffer containing 0·1 mmolar sodium chloride and 0·1 molar potassium chloride. In the final washing solution, there was no change in the concentration of Na⁺ and K⁺, which were thus assumed to be in equilibrium with ions in the membrane fragments. The pellet was then weighed before and after drying at 104° C and was transferred to a 'Vycor' test-tube (Low Na glass) and converted to ash in 2 ml. 'Analar' nitric acid. The ash was analysed for sodium and potassium. The results were corrected for the amount of supernatant which was trapped and were considered to be the amount of sodium and potassium bound.

A very important feature of our measurements is that the binding of Na⁺ and K⁺ was measured in the presence of relatively high concentration of Mg²⁺ and tris ions. The contention is that all the non-specific sites become occupied by these ions, especially by the divalent Mg⁺⁺. When the concentration of Na⁺ and K⁺ is 10⁻⁴ molar, the Mg⁺⁺ concentration is 200 times, and that of the tris ions 300 times, higher; hence we assume that the Na⁺ and K⁺ binding found here is specific.

The figure indicated by the first two methods described is $2-4\times10^{-6}$ moles Na/l. of cells: these methods rely on equilibrium being reached with radioactive Na⁺. With the third method, a much higher value— $2-4\times10^{-6}$ moles of Na/l. of cells—is obtained. It is possible that in this case a large fraction of bound Na⁺ is not readily exchangeable

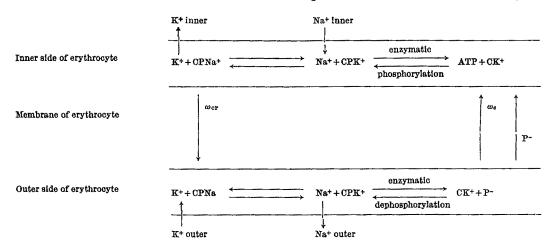

Fig. 1. Model for ion-exchange pump. C, Carrier; CP, phosphorylated carrier; ω , mobility of carrier.

with Na $^+$ in the solution. The results for K^+ are of the same order of magnitude but are more variable than the Na $^+$ results.

Glynn¹⁰ and Solomon et al.¹¹ have calculated from inhibition experiments that the carrier concentration in erythrocytes is about $2 \times 10^{-7} - 2 \times 10^{-8}$ moles/l. of cells. Our results indicate that the amount of specifically bound Na+ is much larger. It can be argued that this large amount is not all required for pump activity but might be related to passive cation permeability. In order to test the effect of ATP on binding, membrane fragments were incubated in a medium of the same composition as that which was used for measuring Na+-K+-ATPase activity. The incubation mixture was left at 37° C for 3 min and the reaction was then stopped, either with boiling ethanol or with cold 5 per cent TCA. The mixture was centrifuged and the residue was washed three times as described for the binding experiments.

Tables 1 and 2 show that ATP increased the binding of Na+ by 50 per cent or more when measured by equilibration of membrane fragments with radioactive Na+. There were no important differences between membranes treated with hot ethanol and those treated with cold TCA. Detailed studies were undertaken using the method of direct analysis of specific binding. Results are shown in Table 3. In all cases a big increase in Na+ binding is seen when membrane fragments were incubated with ATP and Na+ and K+. The omission of K+ from the incubation medium, or addition of ouabain either decreased the effectiveness of the ATP, or else decreased the specific binding below the control values. Similar

Table 1. EFFECT OF ATP ON BINDING OF Na+ BY ERYTHROCYTE MEMBRANE FRAGMENTS

Experiment No.	Treatment	Means by which reaction was terminated	Na bound c.p.m./mg dry weight $\pm S.E$.
1	-ATP	Boiling	42 ± 2.1
2	+ ATP ATP +- ATP	Ethanol	79 ± 1·3 282 ± 25 457 ± 38
3	-ATP		162±14
4	+ ATP - ATP + ATP	5 per cent cold TCA	253 ± 19 202 ± 58 314 ± 15

Membrane fragments (see text) were incubated in a solution containing 30 mmolar tris-hydrochloric acid, pH 7·4, 3 mmolar magnesium chloride, 100 mmolar sodium chloride, 100 mmolar potassium chloride and 3 mmolar ATP for 3 min at 37° C. The reaction was terminated either with bolling ethanol (final concentration 80 per cent) or with cold TCA (final concentration 5 per cent). After centrifugation the pellet was resuspended in solution B (20 mmolar MgCl, and 30 mmolar tris-hydrochloric acid at pH 7·2). After filtration on 'Millipore' filters the filtrand was washed with solution B, and was then equilibrated with solution B, and radioactive Na⁺ was added at a low concentration (10⁻⁵ molar) of Na⁺. After draining, the filter was counted.

Table 2. EFFECT OF ATP ON BINDING OF NA. BY ATP ON ERYTHROCYTE MEMBRANE FRAGMENTS

Treatment		Na ⁺ concentration in the equilibration solution (moles/l.)	Na^+ bound (mole/ml, cells $\pm S.E.$)
- ATP	Native	4×10 ⁻⁴	$11.1 \pm 3.2 \times 10^{-10}$
+ ATP		4×10 ⁻⁴	$19.2 \pm 1.82 \times 10^{-10}$
- ATP	Boiling	1×10-4	5.5 ± 0.82 × 10-10
+ ATP	ethanol		13.6 + 5.2 × 10-10

Membrane fragments were incubated in the same solutions as in Table 1, after which they were either treated with bolling ethanol, or else were centrifuged down. They were then washed three times in solution B (see Table 1). After centrifugation the pellet was resuspended in solution B containing radioactive Na⁺, and incubated for 30 min. After centrifugation, the radioactivity of the supernatant was measured.

Brain microsomes were prepared by the method described by ${\rm 8kou^{14}}.$ Incubation with ATP as described in Table I.

- (a) After incubation with ATP, the microsomes were treated with ethanol, and subsequently as in Table 1 for different experiments.
- (b) After incubation with ATP, the microsomes were treated with 5 $\,\rm pct$ cent cold TCA, and subsequently as in Table 2.

results were obtained for K+, though the effect was usually less.

Preliminary results with rat brain are shown in Table 4. It is clear that results were similar to those obtained from erythrocytes.

It is possible to claim that one step of a chemo-osmotic machine was obtained in vitro, a chemical reaction bringing about an increase in the amount of bound ions. This is an important step in the transduction of chemical energy into osmotic energy. In our experiments, only one step occurred in the cycle of a chemo-osmotic machine, that is, increase in ion binding. The next step to be found should be a chemical reaction which causes the desorption of the bound ions by a decrease in the specific binding capacity.

It is tempting to suggest that there is a close analogy between the effect of ATP on ion binding and its effect on active transport in erythrocytes in vivo as well as on the transport ATPase system in the erythrocyte membrane. In all three cases, addition of ouabain or omission of K abolishes the ATP effect. Our results could thus indicate that the ion pump in vivo might work in the same way as in our experiments. The conclusion that ion binding. which we measured, is connected with the ion pump is reinforced by a correspondence which we have noted between the activity of the Na+-K+-activated ATPase and the degree of binding brought about by ATP. Most of the work reported so far was done on erythrocytes which had been stored for several weeks in the cold in a blood bank. It was found that incubation of the cells with I per cent glucose at 37° C for I h before haemolysis increased by more than three times both the Na⁺-K⁻activated ATPase and the ability of ATP to increase Naand K+ binding (Table 5).

The results obtained here are not consistent with the model of the ion pump presented at the outset, in which there are assumed cyclical alternate changes in Na⁺ and K⁺ binding. The model implies that inhibition by ouabain or omission of K⁺ should increase either the amount of Na⁺-bound substance or the amount of K⁺-bound substance. In our experiments, the addition of ATP appeared to increase both the Na⁺- and K⁺-bound substances. Such a result is consistent with Skou's model^{1,2}, which depicts simultaneous increase of binding of Na⁺ and K⁺ by ATP, but not with the other, generally accepted, model.

Membrane fragments were incubated, as described in Table 1, in a medium containing 30 mmolar tris-hydrochloric acid at pH 7·4, 3 mmolar magnesium chloride and 100 mmolar sodium chloride. 15 mmolar potassium chloride, 3 mmolar ATP and 0·01 mmolar ouabain were added as appropriate. After 3 min at 37° C, boiling ethanol was added and, after centrifugation, the pellet was resnapended and centrifuged three times with cold solution, containing 20 mmolar magnesium chloride, 30 mmolar tris-hydrochloric acid at pH 7·2, 0·1 mmolar sodium chloride and 0·1 mmolar potassium chloride. The pellet was ashed and resuspended in distilled water. S.E. of mean are given. A, B, C, D, E are experiments on different batches of erythrocytes.

Ferric Oxyhydroxide Core of Ferritin

Ьу

P. M. HARRISON F. A. FISCHBACH T. G. HOY

Department of Biochemistry, University of Sheffield

G: H. HAGGIS

Department of Physiology, University of Edinburgh Medical School Ferritin is an iron-protein complex which plays an important part in the storage of iron. Here an atomic structure is proposed for the iron containing core and its synthesis is discussed.

THE characteristic red brown colour of the iron storage protein, ferritin, is caused by the presence of a large amount of ferric iron in the molecule (about 20 per cent of the dry weight). This iron is deposited as (FeOOH)₈ (FeOOPO₃H₂) (ref. 1) within a confined space, about 75 Å across, at the centre of a roughly spherical shell of protein about 25 Å thick²⁻⁴. Native ferritin consists of a mixture of molecules which are unfilled or partially or com-pletely filled apoferritin shells. A high proportion of the molecules contain well filled cores (molecular weight of core about 400,000).

The protein shell has been shown to consist of a symmetrical arrangement of protein sub-units3. electron microscope the cores can be seen without staining. They seem to be rather variable in shape and sometimes to be cleaved into two or more parts5. It is not clear from these studies whether the cleavage seen in the electron microscope has resulted from drying of the sample during examination, or whether the cores are sub-divided into smaller particles in the natural material. The cores give an electron diffraction pattern⁵ indicating that they are composed of crystalline material of average particle size 40 to 50 Å, but again it is uncertain from electron diffraction studies alone whether they are crystalline in the natural state or whether the degree of crystallinity is dependent on the state of hydration. Low angle X-ray scattering from ferritin4 solutions shows that to a resolution of 20 Å the core approximates to a single uniform density object of average diameter 75 Å.

We have now examined ferritin cores under a variety of conditions, wet and dry, by X-ray and electron diffraction, and have obtained essentially the same diffraction pattern both in intensity and line breadth in each case. As previously reported, the electron diffraction pattern of ferritin cannot be identified with that of any of the common oxides or oxyhydroxides of iron. We have considered possible arrangements of oxygen and iron atoms and describe here one which accounts reasonably well for the observed pattern.

The spacings and approximate intensities of bands common to the X-ray and electron diffraction patterns of ferritin are listed in Table 1. A number of small spacing bands were obtained by electron diffraction. Some of these were not clearly visible above the background with X-rays or were beyond the wavelength limit of the FeKa radiation used. Essentially the same pattern has been obtained with all the samples listed in Table 2. The source in each case was horse spleen ferritin, or ferritin reconstituted from horse apoferritin by methods described below. For X-ray diffraction wet samples were mounted in thin-walled glass capillary tubes, while dry powders were pressed into a cylindrical shape with a small amount of gum tragacanth as adhesive.

The results show that iron cores of native ferritin are similar with respect to structure and crystallinity in a variety of conditions (wet or dry, attached to the protein or separated from it). Attention is drawn protein or separated from it). especially to the following observations.

(1) The procedure for separating the cores from the protein (treatment with 1 normal sodium hydroxide for several minutes at room temperature) has previously been shown to remove most of the phosphate from the cores (23 per cent of the original phosphate remaining in the cores, 77 per cent appearing in the supernatant). Cores separated by treatment of ferritin with 1 normal sodium hydroxide for periods up to 2 h gave the same pattern as intact ferritin. The phosphate does not therefore seem to be an essential structural component of the core crystallites, or to contribute significantly to the diffraction pattern. This is confirmed by the result that ferritins, reconstituted from apoferritin by three different procedures, in the absence of added phosphate gave patterns similar to those of the native ferritin (although the crystallites were smaller in some cases). The cores released by alkali treatment also maintain much of their original shape as seen in the electron microscope, although the crystallites of each core become apparently more tightly clumped on removal of protein and the cores aggregate to form a gross precipitate.

^{*} Contained some residual cadmium after crystallization from cadmium sulphate solution.

(2) Powder patterns, typical of ferritin core patterns, could also be obtained from large wet single crystals of ferritin. The most interesting of these are photographs of a stationary single crystal in which sharp spots, caused by the protein crystal lattice, and very weak diffuse rings, caused by the iron cores, can be seen simultaneously. The latter give no indication of preferred orientation with respect to the crystal lattice. This observation supports conclusions, previously derived from comparisons of single crystal photographs of ferritin and apoferritin, that the atomic arrangement within the cores is not specifically related to the structure of the protein. This suggests either that the protein does not have specific binding sites or that, if it does have such sites, the core material is randomly bound to them.

Reconstitution experiments are of some interest in relation to the biosynthesis of ferritin. Details of this work will be published elsewhere, but some points are relevant to this discussion. In vivo evidence suggests that apoferritin is formed first in biosynthesis and indeed the injection of ferrous salts into animals stimulates de novo synthesis of apoferritin. The iron (as

Fe²⁺) enters the intact apoferritin shells, becomes oxidized to Fe³⁺ and is precipitated inside the molecule as ferric oxyhydroxide (FeOOH). The ferric oxyhydroxide crystallites are either bound to the protein or are too large to move out through the spaces between sub-units in the protein shell (which allow the passage of Fe²⁺). Several reconstitution procedures were attempted, of which three are reported here. In each case the starting materials were apoferritin and ferrous ammonium sulphate or ferrous sulphate, the procedure varying as indicated.

(A) Oxidation by oxygen in bicarbonate buffer. pH 6.8 to 8.0 (ref. 9). In the absence of apoferritin this gives

a-ferric oxyhydroxide.

(B) Oxidation by potassium iodate in sodium thiosulphate, pH 5.4 to 7.4. This procedure was first used by Orme-Johnson, Gilchrist and Collins (private communication). In the absence of apoferritin it gives γ -ferric oxyhydroxide.

(C) Oxidation by oxygen in imidazole buffer, pH 6.7 to 7.0. In the absence of apoferritin this gave a third, as

yet unidentified, product.

Reconstituted ferritins (that is molecules which had the usual red brown colour, which had sedimentation coefficients considerably larger than that of apoferritin, and which could be seen in the electron microscope to contain an electron-dense core) were obtained by each of these procedures. Each of them gave a ferritin-like diffraction pattern, although in procedure (A) the crystallites formed inside the protein were considerably smaller than those in native ferritin. Because, in the absence of apoferritin, different products were obtained in each case, the protein clearly has an effect on the mode of crystallization of the ferric oxyhydroxide inside the protein shell. Apoferritin also appeared to affect the rate of oxidation as well as the product obtained. The role of the phosphate, if any, has yet to be determined. Some of it is probably attached to the protein, and may influence the core-protein interaction. Apoferritin is reported to contain some phosphorus¹⁰ (well under half that present in ferritin), but it is not known where this is located. In attempting to interpret the diffraction photographs we have, for the time being, ignored the phosphate and investigated arrangements of oxygen and iron atoms only which might account for this pattern.

The X-ray diffraction patterns of ferritin cores are typical of a rather poorly crystalline material. The lines are broad and weak relative to the background. Densitometer traces were obtained, however, and attempts were made to measure both line breadths and integrated intensities. Crystallite sizes, estimated from the half-width of two lines (spacings, 2.23 and 1.47 Å), are in reasonable agreement within the range of experimental error, for both air-dried precipitated cores and whole ferritin. Qualitative comparisons of the 1.47 band from wet samples indicate similar crystallite sizes under these conditions. The crystallite size, 75 ± 30 Å, obtained from the X-ray patterns is somewhat larger than that estimated from electron diffraction patterns, 40-50 Å. difference may not be significant, but crystallite sizes measured directly from electron micrographs¹¹ appeared to be even smaller, possibly as low as 10-20 Å. Because of the breadth and low intensities of the lines and difficulties in assessing the background, the X-ray intensities could not be measured accurately. Some lines (for example, those with spacings of 1.47 and 1.51 Å) could not be completely resolved from one another on the densitometer trace. On the other hand, the line at about 2.5 Å, which seems, to the eye, to be a single rather broad reflexion, on densitometry could be seen to be composed of at least two overlapping peaks, a strong one at about 2.47 Å and a weaker one at about 2.55 Å. In the electron diffraction patterns a broad, strong line was reported at a spacing of 2.55 Å. This line is measured against a steeply rising background. When re-examined at short exposure times, so that background scatter and

[†] Cadmium free.

peak intensities are reduced, the peak moves to about 2.51 ± 0.03 Å. It therefore seems probable that this line is also composed of two (or more) unresolved lines, as suggested by the X-ray pattern.

As already stated, the diffraction pattern of ferritin cores is not identical to that of any known minerals. It has some similarity, however, to that of δ-ferric oxyhydroxide. The latter has a hexagonal cell with a = 2.94 Å and c=4.51 Å^{12,13}. In the ferritin pattern, strong lines are observed, which would correspond to the (1010) and (1120) reflexions of this cell, but other lines, such as that at spacing d = 1.99 Å, do not fit this simple cell. We can index the ferritin pattern, however, on a hexagonal cell, which has a=2.94 Å and c=9.40 Å (rather more than twice the c axis in δ-ferric oxyhydroxide). The spacings calculated for this cell are compared with the observed ones in Table 1.

The oxides, oxyhydroxides and hydroxide of iron consist essentially of close-packed layers of oxygen atoms, stacked in various ways, with iron atoms in the interstitial holes. These holes are of two kinds, octahedral and tetrahedral, in which the iron is surrounded respectively by six or four oxygen atoms. Octahedral co-ordination of iron is the more common. Fig. 1 shows a structure for the ferric oxyhydroxide of the ferritin core which would fit the hexagonal unit cell described. It has an alternating sequence of four close-packed oxygen layers of the type ABAC ABAC . . . (in hexagonal close-packing there is a sequence of oxygen layers ABAB..., while in cubic close-packing the sequence is ABCABC...). Possible sites for the iron atoms between the oxygen layers are as shown. If the structure is ferric oxyhydroxide, there must be two oxygen atoms for every Fest. In the unit cell in Fig. 1 there are four oxygen sites (we have not distinguished between O2- and OH- oxygen atoms) and a total of twelve iron sites, eight tetrahedral and four octahedral. Various distributions of the two iron atoms among these sites are possible and calculations of expected intensities were made for several of these. agreement was obtained with iron atoms equally distributed among all the available sites in a random manner, so that each site was occupied, on the average, by one sixth of an iron atom. Calculated intensities for this arrangement are shown in Table 1 in comparison with those observed. Lorentz, polarization, multiplicity corrections and a temperature factor, $\exp(-B\sin^2\theta/\lambda^2)$, with B=7.5 Å² have been applied to the calculated intensities. Other arrangements involving variations in the oxygen stacking were also considered (for example, mixtures of cells with ABAB . . . and ABCABC . . . stacking), but none of those tried gave as good agreement between observed and calculated intensities as that

The structure proposed for ferritin has a similar stacking arrangement of oxygen layers to that suggested for "green rust II" (a ferrous ferric oxide hydrate? Fe₃O₄, 4/3H₂O), although the cell dimensions of the latter are larger (a=3.17 Å, c=10.94 Å) and intensity differences suggest that the iron distributions are not identical. In δ-ferric oxyhydroxide the oxygen stacking is of the hexagonal ABAB . . . type with a layer separation of 2.25 Å, and the iron atoms are probably divided among all the various tetrahedral and octahedral sites in the ratio 20-80 per cent. In ferritin cores a higher occupancy of tetrahedral sites may account for the increased separation of oxygen layers, 2.35 Å. There seems, however, to be greater coherence between oxygen layers in ferritin cores than in 8-ferric oxyhydroxide, because in the X-ray patterns of the latter no reflexions with l index greater than 2 are observed as compared with l equal to at least 5 in ferritin. This may reflect a greater degree of hydrogen bonding between layers in ferritin cores, which possibly result from the manner in which the cores are formed inside the protein. Apoferritin, however, may not play a unique part in the formation of

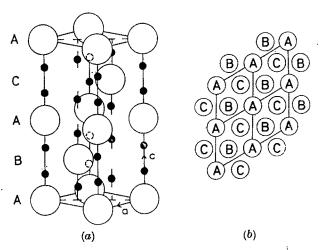

Fig. 1. Proposed unit cell for the FeOOH core of ferritin showing atomic sites.

this structure. Two other diffraction patterns, resembling those of ferritin cores, have been reported; one from a mineral deposited in immature radular teeth of Cryptochiton stelleri14, and the other15 from an iron oxide gel formed by the addition of ammonia to a solution of ferric nitrate (with an estimated crystallite size of 30 Å). These two materials may therefore have structures closely similar to that of ferritin cores.

Further work on ferritin cores is in progress, including a study of fractions of different iron contents.

We thank the Medical Research Council for support (to G. H. H., P. M. H. and T. G. H.), the National Cancer Institute, US National Institutes of Health, for a fellowship (to F. A. F.) and Dr A. L. Mackay for discussion.

Note added in proof. Since this manuscript was submitted, our attention has been called to a recent paper on the constitution of colloidal "hydrous ferric oxide". This material, a hydrolysate of ferric nitrate, also gives a diffraction pattern resembling that of ferritin cores. The authors propose a structure which differs from the one we suggest for ferritin, although the two structures have closely related unit cells. (Towe, K. M., and Bradley, W. F., J. Colloid and Interface Sci., 24, 384; 1967.)

New Type of Restriction to the Expression of a Structural Gene in Bacteria

by M. H. RICHMOND Department of Molecular Biology, University of Edinburgh

Penicillinase synthesis in a strain of Staphylococcus aureus provides evidence for a new type of restriction to the expression of structural

THE expression of structural genes in bacteria may be limited in a number of ways. In some cases, the limitation is expressed by the product of a second-or regulatorygene¹⁻⁸, while in others the rate of expression is set by a region known as the promoter^{7,8}. A third type of limit to

gene expression is found in mutants of the "polar" type⁹⁻¹¹.

In addition to at least the first two of these means of limitation, penicillinase synthesis in Staphylococcus aureus seems to be restricted by the availability of sites at which enzyme synthesis can occur. This type of limitation is only noticeable in cultures which carry two penicillinase structural genes and is shown by the fact that such strains synthesize only as much penicillinase as the haploid strain, and not twice as much, as would be expected on the basis of gene complement. The experiments described here therefore suggest that some cellular differentiation with respect to protein synthesis can exist, at least in these

strains of Staphylococcus aureus.

The expression of two penicillinase genes in a single cell can be studied by using a plasmid diploid clone which contains both the p_A^+ and p_C^+ genes¹² (the genes responsible for the synthesis of A- and C-type penicillinase¹³). This arrangement permits accurate measurement of the expression of each structural gene by immunological techniques^{12,12}. Furthermore, because diploids of this type usually segregate to give both the anticipated haploid segregants, the expression of the same structural genes may be easily studied in the same cytoplasm unaccompanied by a second plasmid¹⁴. The synthesis of A- and C-type penicillinase by the diploid $147(\alpha \cdot i^+p_A^+ \dots \gamma \cdot \text{ero}^R/\beta \cdot i^-p_C^+ \cdot \text{ero}^S)$: for terminology—see Novick and Richmond¹⁴) has been studied, in the presence and absence of inducer, and compared with the synthesis of A-type enzyme by the segregant strain $147(\alpha.i+p_1^*...\gamma.ero^R)$ and of C-type by $147(\beta \cdot i^-p_{\sigma}^+ \cdot \text{ero}^s)$. The results are shown in Table 1. Whereas the p_{λ}^{+} gene is expressed to a level of about 300 U/mg dry weight of bacteria and the p_{σ}^{+} to about 260 U/mg, when fully induced in the cytoplasm of strain 147, the total amount of enzyme synthesized in the diploid $147(p_{\lambda}^{+}/p_{\sigma}^{+})$ is about 290 \overline{v}/mg , of which about half is the immunological A-type variant and half C-type. Clearly, the total penicillinase synthetic ability of the cell is not therefore increased by the presence of two penicillinase genes, and the available penicillinase synthetic ability is shared approximately equally between the two structural genes concerned. In the haploid segregants, however, the full synthetic ability of the cell, with respect to penicillinase synthesis, can be taken over by either structural gene in the absence of the other. As this demonstration of the limitation in penicillinase expression in the diploid is dependent to a great extent on the accuracy of the assay methods used, a series of eight independently isolated diploid clones was tested for their level of penicillinase expression in the presence of inducer and compared with separately isolated segregants of each genotype (Table 2). These results reinforce those shown in Table 1.

Using the known specific enzyme activity of pure penicillinase^{13,15}, calculation shows that a rate of synthesis of 300 penicillinase units/mg dry weight of bacteria is equivalent to about 7.5 µg/mg dry weight of bacteria or to

about 15 µg/mg of cell protein, assuming that about half the cell dry weight is protein. It is difficult to believe that an increase from 1.5 to 3.0 per cent in penicillinase molecules among the cell proteins, which is required for the free expression of two genes rather than one, could not be accommodated by a small reduction in the synthesis of all other proteins, if all the protein synthetic potential in the cell were available for penicillinase production. The limit to penicillinase expression therefore seems to reflect a localized restriction in some component essential for penicillinase but not for total protein syn-

Although these experiments suggest that there is a limit to the amount of penicillinase which can be produced by a staphylococcal cell, they do little to indicate where the limitation occurs. By using certain mutant strains which synthesize very small amounts of penicillinase protein—the so-called "micro-mutants" (ref. 16)—it is possible to investigate more closely the point of limitation in penicillinase formation. Although it is not yet certain that the penicillinase molecule synthesized by the "micro-mutants" is

identical with the wild type, it is certain that the very low level of enzyme activity synthesized by these strains does genuinely reflect the formation of small amounts of protein and not normal amounts of a protein of low specific enzyme activity. So, if a diploid culture is constructed with an $(i^-p_c^+)$ plasmid as one component of a diploid and an $(i^+$ micro-inducible p_{λ}^+) plasmid as the other, it should be possible to decide whether the low rate of expression of the p_A^+ gene (caused by the micro mutation and expressed in a diploid6) allows a correspondingly increased expression of the p_{σ}^{+} gene. In other words, can expression of the p_{θ}^{+} gene in the diploid fill the gap by the very low level of expression of the p_A^+ gene?

The diploid $147(\alpha \cdot i^+)$, micro-inducible $p_A^+ \cdot p_A^+ \cdot$ $\beta \cdot i^- p_{\sigma}^+$ ero⁸) was constructed and its behaviour in the presence and absence of inducer compared with that of the segregants $147(\alpha, i^+)$ micro-inducible p_A^+ . p_A^+ expected from previous experiments16, there was no repair of the micro-inducible phenotype in the diploid: the total amount of A-type enzyme synthesized in the presence of inducer was no more than 2 enzyme units/mg dry weight of bacteria-which is about the same rate of synthesis found in the induced haploid (i+ . micro-inducible p_{A}^{+} segregant. In a fully induced diploid, however, the level of C-type enzyme synthesis was about 135 units/mg-which is about half that found when the same genome was present in the haploid state in strain 147($i^-p_0^+$). Furthermore, this level of expression is similar to that found in the diploid $147(\alpha \cdot i^+p_{\pi}^+\dots\gamma \cdot \operatorname{ero}^n/\beta \cdot i^-p_{\pi}^+\dots\operatorname{ero}^s)$ —see Tables 1 and 2. It seems therefore that the presence of the $(\alpha.i^+$ micro-inducible p_{λ}^+ plasmid restricts the expression of the $(\beta . i^-p_0^+)$ plasmid to about half that found in the haploid segregant $147(\beta . i^-p_0^+)$ despite the fact that little A-type enzyme is synthesized by the diploid. These experiments therefore show that the limitation in penicillinase production in diploid cultures is not caused by competition between penicillinase protein molecules themselves for a limiting site; and accordingly, these results seem to rule out the possibility of a simple competition for a liberation site at the cell surface. The results do suggest, however, that a competition at some level of protein synthesis earlier than the formation of the intact molecule itself does occur—and that this could well be competition between the messenger RNA products of the two penicillinase genes for a restricted number of protein synthesizing sites in the cell.

The possibility that there may be restrictions in the number of sites which are used to express certain structural genes in Staphylococcus aureus raises the question whether this compartmentation reflects the architecture of the staphylococcal cell in any way. Staphylococcal penicillinase is a true extracellular protein¹⁷ (as defined by Pollock¹⁸) which—in the case of the strains used here—is excreted to a limit of about 40 per cent under steady state conditions in media in which the phosphate concentration is high19. Examination of the location of the residual "cellbound" enzyme (60 per cent) shows that about 5 pe: cent may be removed from the cell by washing in 0.6 molar sodium chloride at pH 8.0 but that the great majority of the remaining enzyme is firmly bound to the cytoplasmic membrane. Not more than 2 per cent of the total

penicillinase activity of the cell seems to lie free inside the cytoplasmic membrane—and this small amount could well arise by contamination of the fraction during preparation-particularly because the fractionation requires disruption of intact cells (my unpublished results). It seems probable therefore that staphylococcal penicillinase is synthesized on or in the cytoplasmic membrane, and that expression of the penicillinase structural genes occurs at a limited number of protein synthetic sites in this structure and not generally among all the synthetic sites of the cell.

Although a limitation in the expression of two structural genes in a diploid occurs with penicillinase synthesis in these strains, it is not a universal phenomenon as far as bacteria are concerned, or even for all strains of Staphylococcus aureus. Jacob and Monod¹, Cohn-Bourgeois20 and Revel²¹ have all studied the level of expression of β-galactosidase in diploid Escherichia coli cultures and in all cases there is a reasonable correlation between enzyme activity in the culture and the complement of β -galactosidase structural genes. Even in Staphylococcus aureus strain PS 80 (ref. 22) the synthesis of penicillinase in diploid cultures may reflect the number of penicillinase structural genes in diploids in certain circumstances (unpublished work of E. H. Asheshov and K. G. H. Dyke). In both the β-galactosidase and penicillinase diploids, however, where there is no restriction on enzyme expression, one genetic component of the diploid is chromosomal and the other extrachromosomal. In the penicillinase diploids described here, where restriction does occur, both the penicillinase structural genes are carried in the extra-chromosomal state on plasmids, and this may be related to the limitation in gene expression.

If the synthesis of certain proteins is restricted to certain regions in the bacterial cell, the question immediately arises as to how this is achieved in molecular terms. One possibility is that message synthesis occurs only in a restricted region in the cell and that widespread diffusion of the message to all parts of the cell is impossible. In view of the apparent restriction of penicillinase synthesis to a limited number of sites in some staphylococcal strains, it seems possible that these sites may provide a stimulus to allow message transcription from the gene to occur, but only when the gene and the relevant protein synthesizing sites are in the correct spatial juxtaposition. If this hypothesis is correct, it implies that the positional relationship between various portions of the bacterial genome and various sites of protein synthesis in the cell could well be of crucial significance to the functional differentiation of bacterial cells.

LETTERS TO THE EDITOR

PLANETARY SCIENCE

Ionospheric Effects caused by Electrons precipitated from the Outer Radiation Belt

DURING the period October 1962 to March 1963, there was a disturbance in the ionosphere at the Antarctic station Sanae (70° 18' S., 2° 22' W.) whenever a high flux of precipitated electrons was observed in the magnetically conjugate area by the satellite Alouette1. Together with Gledhill, we' have shown that similar disturbances are produced at other stations lying near the same magnetic shell (L=4) in both the northern and southern hemispheres. We established that flux values above a certain level are observed only when the ionosphere is disturbed, and that the percentage of total time for which this level is exceeded at each station is almost exactly the same as the percentage time for which the ionosphere is disturbed. Our results showed that the frequency of occurrence of ionospheric disturbances on L=4 increases markedly in the vicinity of the South Atlantic geomagnetic anomaly. This observation was attributed to the fact that the mirror points of particles trapped in the outer radiation belt are much lower there than anywhere else, being responsible for the high intensities of charged particles observed there3,4.

There seems no reason why the effects² should be confined to the shell L=4. Several workers³⁻⁶ have observed high counting rates of charged particle fluxes at shells as low as L=2. It has also been observed⁷ that electron bombardment makes a contribution to the ionization of the F region in the South Atlantic both by day and night, and it has been suggested⁶ that the "winter anomaly" in D region absorption could be explained by mid-latitude electron precipitation. It therefore seems probable that electron bombardment could be an important cause of ionospheric disturbances at all sites which lie below the outer radiation belt. Unfortunately, satellite observations are not available to us at present for these locations, so this theory cannot be directly tested. Here we use the facts already established² to extend the treatment to lower L shells.

The behaviour of the ionosphere was examined at each of a large random sample of 2 h periods at several northern and southern hemisphere stations lying on the shells $1.88 \leqslant L \leqslant 4.47$ for the period October 1962 to March 1963. The percentage of total time for which the ionosphere was disturbed at each station was determined using the previous method¹. We have, however, made one change. We included the parameter f_0F_2 so that the ionosphere is classified as disturbed if any one of the three parameters f_{\min} , $h'F_2$ or f_0F_2 lies outside the calculated undisturbed range.

One of the shortcomings of this method is that the disturbances do sometimes occur on magnetically quiet days, and as a result of this the selection of the undisturbed range is not definite. We are at present improving this method and so the values given here should be regarded as relative. The results are shown in Tables 1 and 2. The results for the six stations examined previously² are also shown. In the case of Marion Island, data for the period October 1957 to March 1958 were used, because these are the only data in our possession for this station.

It is clear that the frequency of occurrence of ionospheric disturbances does increase over the South Atlantic geomagnetic anomaly, as is the case for L=4. In the light of previous results¹, this strongly suggests that the correlation between electron flux and ionospheric disturbances found at L=4 will persist at all sites which lie below the outer radiation belt. A detailed study of latitudinal longitudinal, seasonal and diurnal variations is being carried out at present.

It has been shown that the frequency of ionospheric disturbances increases markedly over the South Atlantic We should therefore expect the geomagnetic anomaly. frequent occurrence of this phenomenon to be reflected in the normal behaviour of the ionosphere in this region. This implies that a longitudinal variation should be found in the behaviour of the ionosphere at locations below the outer radiation belt. (The parameters f_{\min} and $h'F_{\perp}$ were unsuitable for direct comparison of values at various stations, because f_{\min} is dependent on the instrument used and $h'F_2$ could give misleading results because it is not simply related to the real minimum height of the F_z layer.) To investigate this theory we have used monthly world-wide radio prediction charts issued by the Central Radio Propagation Laboratories. From these maps it is possible to read values of the maximum usable frequency for propagation at vertical incidence (MUF(0)) at any desired location. Because MUF(0) is actually f_xF_2 , the extraordinary wave critical frequency of the F2 layer MUF(0) is equal to $f_0F_2+f_H/2$, where f_H is the gyro frequency at a given location.

MUF(0) charts available to us at present cover the period May 1963 to July 1967. We therefore chose to examine data for May 1963, this being the month nearest to the period studied. In Fig. 1, MUF(0) at local midnight is plotted against longitude for various values of L. In order to compare F_2 region behaviour in the anomaly with that elsewhere, we also plot MUF(0) against longitude for the northern hemisphere. In this case, we use data for November 1963 which is the corresponding seasonal period. We restrict our attention to the night-time period which is best suited for a study of electron induced effects, because, as far as is known, there are no other causes of ionization operative then.

Also marked on each curve is the longitude of minimum geomagnetic intensity, B_{\min} , indicating the longitudinal centre of the geomagnetic anomaly.

The southern hemisphere curves show unmistakably that MUF(0) decreases in the region of B_{\min} , passes through a minimum and then rises to a maximum to the west of the lowest B. The minima also move westward with B_{\min}

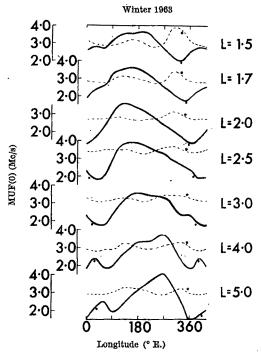

Fig. 1. Longitudinal variation of MUF(0) in the northern (---) and southern (---) hemispheres along various L shells at local midnight.

towards lower L shells. As is to be expected, the longitudinal variation of MUF(0) is very much less pronounced in the northern hemisphere, as the anomalous decrease in geomagnetic intensity is not very marked there. There are also two peaks in the northern hemisphere. One is approximately conjugate to the southern hemisphere minimum. This peak becomes more pronounced at lower L shells and at L=1.2 the northern hemisphere variation is larger than that in the southern hemisphere. It practically disappears at L=3 where the precipitated electron flux intensity was observed to decrease during the period May to July 1963 (ref. 5). Another peak is also discernible at about 150° E. which corresponds with the small increase in precipitation observed there3.

The southern hemisphere variations observed in MUF(0)are greatest in magnitude at L=5; there is a decrease towards L=3, an increase at L=2 and then a decrease again toward lower L values. This is consistent with the variation of precipitated electron flux intensity across L space for May to July 1963 (ref. 5). Preliminary analyses of the same type for other times of day, year and solar cycle indicate that the same behaviour persists during the six summer months, but not during winter. A detailed investigation of these phenomena is being carried out at present.

An explanation of the causes of this phenomenon will not be attempted here. Preliminary results, however, suggest that corpuscular bombardment of the atmosphere may give rise to two competing effects: an increase in electron density because of direct ionization, and a decrease in electron density because of a temperature increase which may increase both the scale height and the effective recombination rate.

Cavernous Weathering in the Taylor Dry Valley, Victoria Land, Antarctica

TAYLOR VALLEY (77° 33' S., 163° 25' E.) is part of a deglaciated valley complex called the McMurdo Oasis, which is located about 80 km to the west of Ross Island across McMurdo Sound. Since the IGY many New Zealand and American geological parties have worked in this area1-3, which is easily accessible by helicopter from Scott Base and McMurdo Station at the southern end of Ross Island. Now that the topographical and geological reconnaissance stage has been completed and adequate maps cover the 2,500 km² of the McMurdo Oasis, more attention is being devoted to the study of various anomalies and problems.

One interesting geomorphological phenomenon, found in the Taylor Valley, is the cavernously weathered granite and gneiss erratic boulders (or taffonis). Processes of physical weathering which occur in this cold desert area are more involved, and probably more rapid, than has previously been imagined. Rock disaggregation in the McMurdo Oasis is not simply explained by the processes of freeze and thaw or wind, and evidence is mounting concerning the part which growth of soluble salt crystals plays in the development of cavernous weathering.

To establish the basis for more detailed studies, the important concentration of cavernously weathered erratics was mapped during autumn 1966 (Fig. 1). Many of the

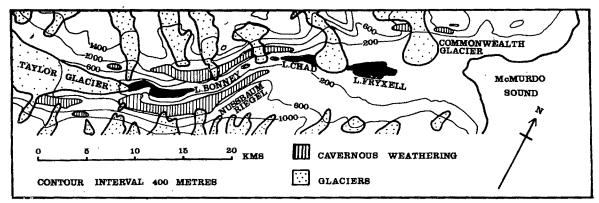

Fig. 1. Taylor Valley, Victoria Land, Antarctica, showing distribution of principal areas of cavernously weathered erratic boulders.

boulders observed were more than 2 m in height and were from 4 to 5 m in diameter, with pits from 1 to 2 m in diameter which rose gradually inwards. As weathering proceeds, however, the boulders are progressively lowered to a deeply pitted stage of coalescing disintegration, with the upper part being completely removed. As was observed in the Victoria Valley, no preferred orientation of honeycombing was noticed4.

Weathering processes in this locality have to be assessed against the nature of the environment and its climate. Taylor Valley extends for 40 km from the Taylor Glacier to McMurdo Sound (Fig. 1). Taylor Glacier which drains from the polar plateau is a former outlet glacier but now penetrates only a short distance into the valley. Tongues from several alpine glaciers descend into the valley from either side, and during the summer period streams of melt water drain into highly saline lakes, such as Bonney, Chad and Fryxell. Nussbaum Riegel (1,000 m) divides the valley into a lower, and more open, eastern section, and an upper, and more narrow, western section.

Taffonis chiefly occur in the upper Taylor Valley (Fig. 1) and, although they are found in the lower Taylor Valley, they do not appear with the same intensity, except for two small areas on either side of the Commonwealth Glacier. This disparity in location of taffonis is probably caused either by lack of erratic boulder deposition in the lower Taylor Valley, or by their removal or destruction by subsequent ice advances from the direction of McMurdo Sound. In the upper Taylor Valley, taffoni concentration is predominantly on a broad moraine covered bench, on the south side of the valley, 200 to 600 m above sea level, which runs from Nussbaum Riegel towards the Taylor Glacier, and on narrow benches, on the north side of the valley and at similar heights, which are broken by the tongues of the steep alpine glaciers as they descend towards the valley floor (Fig. 1). In some places, taffonis are located close to the snouts of these alpine glaciers, which indicates that the regimes of these glaciers were sluggish, even during the late Pleistocene.

Multiple glaciation has occurred in the Taylor Valley, and the moraines on which the taffonis lie were probably deposited during Péwé's Taylor Glaciation⁵ and Calkin's Bull Drift Episode of his Victoria Glaciation, to which he

has put a minimum age of 30,000 yr6.

In relating weathering forms to climate there is still a great lack of information on the heat balance of this area. It is known, however, that the mean annual temperature is in the vicinity of -17° C, although summer temperatures are usually in the range -4° to 0° C, and at times the air temperature can reach 10° C and ground temperatures over 20° C. It has been shown that in the active layer of the soil in this area, some twenty to sixty freezethaw cycles occur each year?. Precipitation, or snow accumulation, totals about 15-20 cm a year near the lower end of the Taylor Valley and tends to decrease as one moves inland. A strong positive radiation balance for the area of about 29,000 cal cm-2/years, however, soon disperses any snowfall, and indeed evaporation tends to continually enlarge the ice free area, with the low albedo of the bare rock surfaces causing an increase in summer temperatures and a decrease in relative humidity.

Winds blow predictably up or down valley and show a seasonal alteration. During summer, easterlies pre-dominate and are cooler and more humid than the drier katabatic westerlies which predominate in winter and are heated adiabatically in their rapid descent from the polar plateau of the continental interior. During summer, the influence of these warm, dry westerly winds is largely confined to the upper part of the Taylor Valley. The sublimating character of these westerly winds also tends to keep the valley snow free, even during the winter months. Although reliable comparative data are lacking, the upper part of the Taylor Valley, which is where the best examples of cavernous weathering exist, is a drier and a less cloudy and humid area than the lower part of

the valley where consequently rates of evaporation and sublimation seem to be less.

The existence therefore of favourable environmental conditions plus a plentiful supply of salts has led to the conviction that salt weathering is the dominant erosive process in the McMurdo Oasis. Other physical processes such as the influence of the wind can certainly no longer account for the development of cavernous weathering10, and frost fracturing is effective chiefly at the permafrost level and in areas open to insolation, whereas the development of salt crystallization favours the shady and sheltered situations of pits and hollows. In Corsica, where taffoni form resembles those in the McMurdo Oasis, it is noted that taffonis are commonest near the coast, where there is a plentiful supply of salt with only one weak frost a year, but at higher altitudes where there is a diminished salt supply but greater frost action, taffoni formation soon disappears11. Laboratory experiments have shown12 that crystallization of salts, such as sodium chloride and gypsum, can exert disintegrating forces in excess of rock strength when rapid cooling or evaporation produces a small degree of supersaturation.

The origin of the widespread occurrence of salts throughout the McMurdo Oasis has been under discussion^{7,13}, but it now seems probable from a trace element study of lakes in the McMurdo Oasis14 that the salts were principally extracted from continental rocks by glaciers and were fed into the lakes by streams of melt water during the summer. Origin apart, rock breakdown of the coarsely crystallino erratics begins to develop when the crystallization point of one of the salts is reached. The process is quite distinct from chemical weathering and does not seem to lead to widespread mineral alteration 10,15,16. Future investigations should, however, provide more relevant data with regard to the nature of the rock meal found in the interior of taffonis, and also make available more macro- and micro-climatic information, particularly on the mechanics of microgelivation and supersaturation.

Large Scale Earth Resistivity Experiment in New Zealand

In 1965 a high voltage d.c. line, 580 km long, began operation, bringing power from the Benmore hydroelectric power station in the South Island of New Zealand to the Haywards terminal in the North Island (Fig. 1). Initially, the return path of the current was through the ground from which an approximately dipole pattern of potential might be expected on the Earth's surface. This potential would not in general be separable from other ground potentials of natural or artificial origin. Load changes in the Benmore-Haywards system are, however, carried out in steps of 20 MW, or 80 amp in line current. The consequent abrupt changes in ground potential can be observed for considerable distances from the electrodes provided there is no great telluric activity at the time.

These measurements have been used to investigate ground resistivities, the method being similar in principle to normal resistivity surveying but on a much larger scale. The New Zealand Electricity Department agreed to a programme of 20 MW load changes after midnight, when other earth current activity is at a minimum. Potentials were measured between orthogonal pairs of iron spike electrodes about 800 m apart. Observations were successfully obtained at forty-eight stations, chiefly in the South Island, and the results are shown in Fig. 1.

There is clearly an overall pattern which, however, departs considerably from a simple dipole. The most noticeable feature is the marked difference in the patterns around the two electrodes. The northern electrode is in good contact with the sea and vectors in its vicinity are small and varied in azimuth. In contrast, the Benmore electrode is sited in the middle of the South Island, where the chief rock types are schist, greywacke and argillite. The large radial gradients indicate a more resistive and

uniform medium here. On this pattern is imposed considerable variation in azimuth and amplitude, much of which is likely to be caused by near surface inhomogeneities. For example, accessible sites were frequently down in valleys rather than on exposed ridges, and the shape and conductivity of the valley sediments could well affect the current vector.

Observations around the southern electrode are sufficiently regular to be discussed in terms of a unipolar model. If a current of I amps flows into a uniform half space of resistivity ρ , from a point source on the surface, the surface potential gradient is

$$E = \frac{\rho I}{2\pi r^2} \text{ volt/m}$$

at a distance r metres from the source. Twenty-four stations have been selected as reasonably close to Benmore to be largely unaffected by the northern electrode. The observed values of the gradient are shown in Fig. 2, plotted against distance from the Benmore electrode. The dashed lines are the theoretical curves for a homogeneous medium with resistivities of 2,500 and 5,000 Ω m.

There is some systematic variation here. The gradients for stations more than 100 km distance from Benmore are

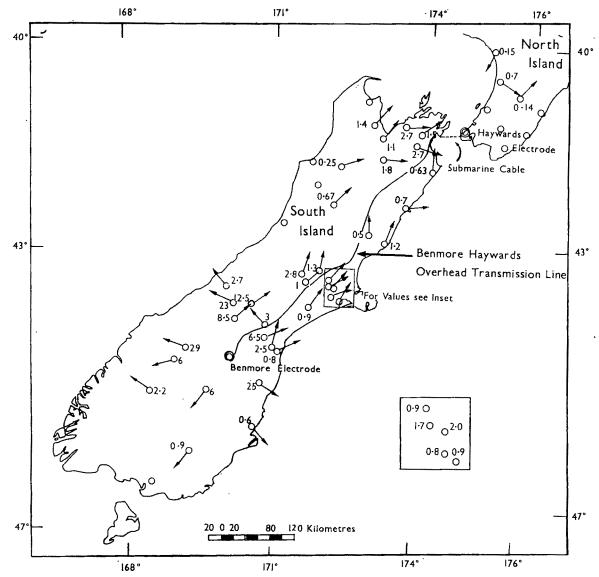

Fig. 1. Map showing positions of the two electrodes and the field stations. The arrows indicate the direction of maximum potential gradient at the station which is situated at the base of the arrow. The figures are the values of the potential gradient in mV/km. Circles without arrows indicate stations where no recognizable change in signal occurred on switching. Directions assume current entering ground at Benmore electrode.

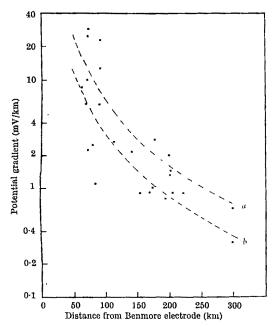

Fig. 2. A plot of the resultant potential E against distance from the Benmore electrode. The change in current flowing is 80 amp in all cases. The theoretical curves for $\varrho=5,000~\Omega m~(a)$ and 2,500 $\Omega m~(b)$ are shown.

less scattered than for stations closer to the electrode, again suggesting lateral inhomogeneities nearer the surface. The apparent resistivities, computed from the formula given previously using the observed gradients, range from 1,500 to 15,000 Ωm with a mean of 5,000 Ωm . These are rather high values but are not inconsistent with soundings in similar depths elsewhere. Lundholm¹ found resistivities of 14,000 Ωm beneath Sweden, and Krajev found resistivities of 2,000 Ωm beneath Karelia², with dipole separations of up to 600 km and 75 km, respectively. Cantwell, Nelson, Webb and Orange³ found values usually less than 1,000 Ωm for separations of up to 200 km in north-west United States.

The depth of penetration of the current is affected by the presence of the sea but must be several tens of kilometres at least under the South Island. The resistivity contrast between the Benmore region and the sea is of the order of 10,000 to 1, and suggests that to a first approximation the sea may be an equipotential. Deeply penetrating currents from the southern electrode would return then to the northern electrode through the sea bed and the sea. The observed surface vectors do not, however, fully support this and show some tendency to a dipole flow pattern. Further work is in progress.

Age of the Paresis Complex, South-West Africa

MESOZOIC igneous activity in South-West Africa is shown as lava plateaux and dyke swarms of basaltic composition and as a group of central volcanic complexes representing a highly variable range of rocks¹. The Paresis complex (20° 15′ S., 15° 42′ E.) is one of the latter and is made up of a consanguineous suite of syenites, bostonites, rhyolites and associated foyaitic rocks, as well as minor basalts and gabbros. From structural and geochemical evidence Siedner²³ concluded that the basaltic rocks of Paresis represent locally preserved remnants of the regional Stormberg volcanics coeval with, but genetically unrelated to, the central felsic suite. The age of Paresis is thus significant because it dates both the complex and the regional volcanism. The only other published chronological datum on Mesozoic igneous centres in South-West Africa is a potassium-argon age of 190±8×10° yr on biotite from the Klein Spitzkop granite⁴.

For this study five quartz-bearing members of the central igneous suite, previously described and analysed3, were selected. Rubidium and strontium concentrations were determined by stable isotope dilution on a 6 in. mass spectrometer, and the isotopic composition of strontium was measured on a 12 in. mass spectrometer. In calculating the data it was assumed that the rubidium-85/rubidium-87 ratio of natural rubidium is 2.591 (ref. 5) and the strontium-86/strontium-88 ratio of natural strontium is 0·1194 (ref. 6). The strontium-87/strontium-86 ratios were normalized to strontium-86/strontium-88 = 0.1194. The errors are estimated to be 2 per cent in the rubidium-87/strontium-86 ratios and 0.05 per cent in the strontium-87/strontium-86 ratios. A straight line (Fig. 1) was fitted to the data (Table 1) by the method of York?. The weights assigned were the reciprocals of the squares of the estimated errors. The slope of the fitted line is 0.001872 ± 0.000060 from which the age of $135 \pm 4 \times 10^8$ yr was calculated, assuming $\lambda = 1.39 \times 10^{-11}$ yr⁻¹ (or 127 ± 4×10^6 yr if $\lambda = 1.47 \times 10^{-11}$ yr⁻¹). The intercept at rubidium-87/strontium-86 = 0 is 0.7086 ± 0.0014 . All the errors quoted are 99.5 per cent confidence limits. A potassiumargon age of 136×106 yr on a basalt from Paresis8 supports the present results.

Table 1. RUBIDIUM AND STRONTIUM CONCENTRATIONS AND ISOTOPE RATIOS OF ROCKS FROM THE PARESIS COMPLEX

210

	56·1 16·4	16·4 64·4 12·1 93·7

The Mesozoic volcanics of South-West Africa are, on stratigraphic grounds, usually correlated with the Stormberg Series of the Southern African Karroo System. Recent age measurements on rocks from Rhodesia^{9,10}. South Africa^{10,11} and Swaziland¹² confirm the Triassic to early Jurassic age of the Stormberg volcanism in those areas. Data reported here and elsewhere⁸ indicate that the climactic phase of Mesozoic volcanism in South-West

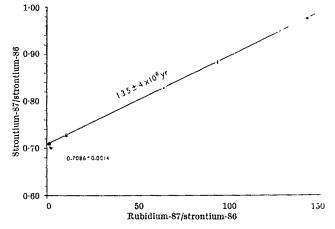

Fig. 1. Total rock isochron for a differentiated suite from the Paresis igneous complex, South-West Africa.

Africa, however, occurred between 110 and 135×10^6 yr ago. The apparent interval of at least 40×10^6 yr between the formation of the Stormberg volcanics in these two broad regions raises serious doubts about their stratigraphic equivalence. Age determinations on these rocks are unfortunately still too few and discontinuous to justify a high degree of confidence about the chronological pattern of the Stormberg volcanism in southern Africa and the nature of its westward migration. Further ageinvestigations on Mesozoic basalts from South-West Africa, Lesotho and Rhodesia are in progress.

Life on the Surface of Venus?

It is said (for example, refs. 1-3) that our knowledge of the surface of the cloud covered planet Venus is extremely fragmentary and ambiguous; that there are alternative non-thermal explanations of the microwave emission; that, even if the surface is hot, the polar regions may be cold enough to support life, or sufficiently high mountains may exist, and so on. It seems appropriate to relate some of this speculation to continuing work on the

physical environment of Venus.

The principal objection to life on the surface of Venus is the high inferred temperatures. Ground-based measurements of the disk-integrated microwave brightness temperature as a function of wavelength4-6 and of phase angle7, as well as radio interferometry^{8,8} and the Mariner 2 microwave experiment^{10,6}, all have a simple and natural interpretation if the surface of Venus is a hot dielectric sphere with mean thermometric temperatures of about 700° K. A comparison of the radar and visual diameters of the planet combined with the most likely temperature structure of the atmosphere, within the range of probable errors, again suggests 700° K (ref. 11); this argument is independent of passive microwave results. The agreement among these different modes of measurement is striking. Those alternative, non-thermal, explanations of the microwave emission which have been made in sufficient detail to be tested disagree seriously with one or more of the microwave observa-This includes free-free transition models of ionospheric emission^{10,12}, synchrotron radiation from presumed Van Allen

radiation belts9,13, glow discharges as a result of charge separation¹⁴ and electrical discharge between adjacent liquid droplets in the clouds¹⁴. Some other non-thermal model may explain the microwave observations, but no such model yet exists. Although it has been difficult to account for the high surface temperature, recent developments in the construction of non-grey greenhouse and other atmospheric models have made possible successful generation of the requisite surface temperatures.

There has been speculation³ that the appearance of Earth as photographed by Lunar Orbiter 1 is sufficiently similar to that of Venus to suggest that the surface environments of the two planets are also similar. Fig. 1 compares photographs of crescent Earth and crescent Venus. At optical frequencies the overcast of Earth is about 50 per cent, and the overcast of Venus almost 100 per cent. No unambiguous breaks in the clouds of Venus have ever been reported. While the visible clouds of Venus certainly play a part in maintaining the high surface temperatures15, infrared absorption by the atmosphere must contribute much more to the total opacity in any successful greenhouse model. Thus not only are the cloud covers very different for Earth and Venus, but cloud cover is not a very useful criterion for comparing surface temperatures.

The conclusion that the surface is very hot is still inferential, and direct measurements by atmospheric entry probes are certainly needed (see addendum at end of communication). The complete evidence, however, strongly suggests average surface thermometric temperatures of about 700° K. In such hot surface models, the coldest spots will be at the poles; temperatures there can be estimated from interferometric observations and from symmetry arguments as $470^{\circ} \pm 95^{\circ}$ K (refs. 7 and 8). Even the polar temperatures are therefore probably above the normal boiling point of water. There are some radar data suggesting mountains on Venus, although it is actually areas of enhanced local roughness which have been found. The maximum possible lapse rate of temperature in the lower Venus atmosphere is the adiabatic, about 8° K/km. A mountain top in a typical locale with a temperature of, say, 350° K would have to be some 44 km high. Such mountains are impossible on Venus-the hydrostatic pressures at their bases exceed the tensile and yield strengths of all geochemically abundant materials. This problem even applies to hypothetical mountains at the poles of Venus.

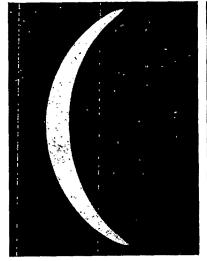

Fig. 1. Left: photograph of crescent Venus in integrated visible light (courtesy, Mt. Wilson and Palomar Observatories). Right: photograph of crescent Earth in integrated visible light by the ATS-1 satellite (courtesy, Goddard Space Flight Center, NASA). The surface resolution of Earth is here several times better than for Venus, but the contrast discrimination is worse. It is clear that, if the resolutions and shades of grey were degraded to the same level, surface detail would be visible on Earth and not on Venus.

The critical point of water is 647° K and 218 atm. Thus liquid water is impossible at average Venus surface temperatures. At the deduced polar temperature near K, the saturation vapour pressure over liquid water is 83 atm. In most models of the atmosphere of Venus the total pressure is less than this 16. Furthermore, the opacity at millimetre wavelengths caused by even I atm of water vapour would be grossly inconsistent with the microwave spectrum (compare refs. 4-6). Large quantities of water vapour are also inconsistent with the observed radar reflectivities. At cold spots the water vapour partial pressure is at most 1 per cent of the saturation value, and probably less.

Enzymes are rapidly inactivated, proteins denatured, and most biological organic molecules pyrolized at temperatures much less than 700° K, and so it seems safe to conclude that the mean surface temperatures of Venus exclude terrestrial forms of life. Alternatives such as biological refrigerators pumping heat across the surface boundary layer temperature gradient can perhaps be imagined, and some thermodynamic studies along these lines may be useful, but the overall chances of life on the surface of Venus remain bleak. The possibility of life in the clouds has already been discussed?

Addendum.The recent success of the Venus 4 spacecraft of the Soviet Union supports the conclusions reached here, which were written before the entry of the Venus 4 capsule into the atmosphere of Venus. Surface temperatures of 550° K near the nightside equator are roughly consistent with the interferometric and phase observations7,8; but because these temperatures are somewhat smaller than the microwave results, the strictures against life at the very poles may be slightly relaxed.

This work was supported by grants from NASA and the Alfred P. Sloan Foundation. I thank Mr R. R. Drummond of the Goddard Space Flight Center, NASA, for providing the ATS-1 photograph.

PHYSICS

Relationships between the Masses of Subatomic Particles

In previous communications^{1,2}, I have shown that all subnuclear particles are probably composed of x tamaids combined with y bachs according to definite quantum conditions controlled by a quantum number z. In the

case of positively charged subatomic particles I developed a relationship as follows

Particles external to the core = (x-6)+y=(3+13z) (1)

One of the most remarkable features of the tamaid-bach stationary states is that the experimental data support the conclusion that there can be a facile interchange of tamaids and bachs as between the core and the external stationary states. I consider it very probable that the cores of subnuclear particles of positive charge contain a constant number of six entities regardless of their physical nature, the stationary states containing either three units or successive shells of thirteen unit particles in conformity with equation (1).

The structures indicated in Table 1 follow for the common mesons, baryons, etc., t^0 being the tamaid and b the bach.

Table 1. CHARGED SUBNUCLEAR PARTICLES

Symbol	z	Mass (MeV)	Core	First shell	Second shell	Third shell	Fourth shell	Fifth shell
$\mu^+ \ \pi^+ \ \mathrm{K}^+$	0 2 1	105·659 139·57 493·78	$ \begin{array}{r} 4t^0 + 2b \\ 5t^0 + 1b \\ 6t^0 \end{array} $	3b 3b 3b	13b 13t°	13b		
Q+ D Σ+	3 3 4	758-30 938-256 1,189-53	6t° 6t°	3b 3b 3b	13t° 13t° 13t°	$10t^{0} + 3b$ $13t^{0}$ $13t^{0}$	$13b$ $4t^{0} + 9b$ $13t^{0}$	1t° + 12b

The structures for the muons and the pi meson are particularly interesting because they imply the existence of bachs in the core.

It is known that modern atomic theory does not accept the presence of the electron within the atomic nucleus because of its large de Broglie wavelength, and it is also known that the neutron can nevertheless decay to give an electron. It is, however, improbable that, in the core of a subnuclear particle, a single bach combines with a single tamaid to form an entity comparable with the neutron because, according to the quantum equation (1), all the bachs seem to exert their specific influence even when they are apparently in the core.

Whether the shells given in Table 1 are characteristic of true orbitals or whether the various particles merely agglomerate in quantized layers is a matter for future speculation.

Some of the masses of certain subnuclear particles have been determined by various workers with very considerable precision3, and these have been used in Table 2 to give the best statistical value for the rest-masses of the bach and tamaid in MeV units, the normal method of least-squares analysis being employed. It is very unlikely that the bound mass of the tamaid remains absolutely constant, and this must affect the accuracy with which the absolute value of the mass of the bach can be determined.
